

## Transmeta Architecture

- Major Ideas
- General Architecture
- Emulated Precise Exceptions
- What to do with It

1

## Background

- Transmeta Corporation
  - Paul Allen (Microsoft), George Soros (Soros Funds)
  - David R. Ditzel (Sun) Chief Tech Officer
  - Edmund J. Kelly, Malcolm John Wing, Robert F. Cmelik
  - Linus B. Torvalds, February 1997 → ...
- Patent 5832205
  - applied August 20, 1996
  - granted November 3, 1998
  - many (a few) other patents ...
- Crusoe processor
  - published January 19, 2000

## Basic Idea(s) <sup>(5)</sup>

faster

cheaper

- Create a new processor which, when coupled with “morph host” emulator, can run Intel/Windows code faster than state-of-the-art Intel processor, *or* with same speed but with less electric power
- New processor can be implemented with significantly fewer gates than competitive processors
- Compete with Intel, friendly with Microsoft
  - sell chip with emulator code to system manufacturers (Dell, IBM, Sun, etc etc)
- x86 binary is new binary standard
- Native OS not so important
  - could be Linux

3

## Major General Ideas

- Emulation can be faster than direct execution
- TLB used to solve new problems
  - track memory accesses for memory mapped I/O
  - track memory accesses for self-modifying code
- Most of executed code generated “on-the fly”
  - not compiled before execution begins
  - extremely optimized dynamic code generation
- Optimized code allows for simpler machine
  - smaller, faster, uses less power?

4

## Major General Ideas (contd)

- Self-modified code (dynamically created code) can be generated so that it is extremely optimized for execution
  - issue dependencies, reorder, reschedule problems solved at code generation (not in HW)
  - processor does not need to solve these
- Optimize for speed only when needed
  - do not optimize for speed when exact state change is required (this is the tricky part!)
- Alias detection to assist keeping globals in registers

5

## Major General Ideas (contd)

- NOT: faster and with less power

Class action suit (27.7.2001) ... stating that ... a revolutionary process that delivered longer battery life in Mobile Internet Computers while delivering high performance ....

6

## Major Emulation Ideas

- Target processor (I.e., Intel processor) state kept in dedicated HW registers
  - working state (“speculated” state?), committed state
- Memory store buffer keeps uncommitted (“speculated”) emulated memory state
- Specific instructions support emulation
  - commit, rollback (exact exceptions)
  - prot (aliases)
- TLB (and VM) designed to support emulation
  - A/N-bit (mem-mapped I/O), T-bit (self-mod. code)

7

## General Architecture

- VLIW implementation
  - VLIW = Very Long Instruction Word
  - 4 simultaneous RISC instructions
    - one each of float, int, load/store, branch
  - no circuitry for issue dependencies, reorder, optimize, reschedule
    - compiler takes care of these
  - what about data, control and structural dependencies?
    - part of issue dependencies?
    - data & structural dependencies under compiler control?

17/10/2001

8

## General Architecture (contd)

- Large register set
  - native regs: 64 INT, 32 FP
    - extra regs for renaming
  - target architecture regs: complete CPU state
    - INT, FP, control **Reax, Recx, Rseq, Reip**
    - working regs for normal emulation
    - committed regs for saving emulated processor state

9

## General Architecture (contd)

- TLB
  - new features to solve new problems
    - before used to solve also memory protection problems in addition to plain VM address mapping
  - A/N-bit for memory-mapped I/O detection
    - trap to emulator, which creates precise code
    - memory-mapped I/O requires precise emulated processor state changes
  - T-bit for self-modifying code detection
    - trap to emulator, which recreates emulating code in instruction cache (“translation buffer”)

17/10/2001

10

## General Architecture (contd)

- Target memory store buffer
  - implemented with special register(s) to support emulation
  - keeps track on which target processor memory stores are committed and which are not
  - uncommitted memory stores can be discarded at rollback
    - modify HW registers implementing it
    - commit & rollback controlled from outside of the processor, not internally as is usual with speculative instructions

17/10/2001

Copyright Teemu Kerola 2001

11

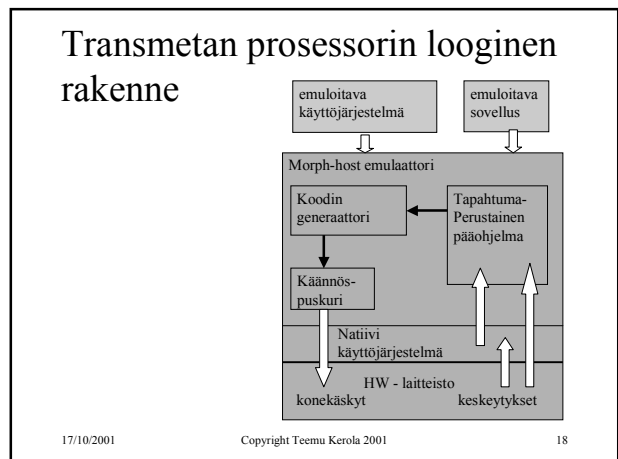

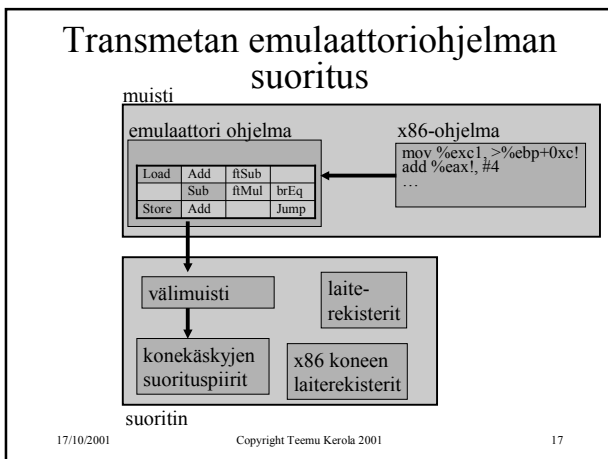

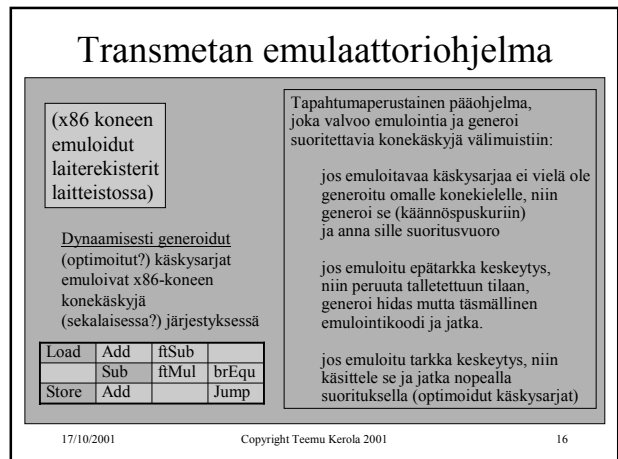

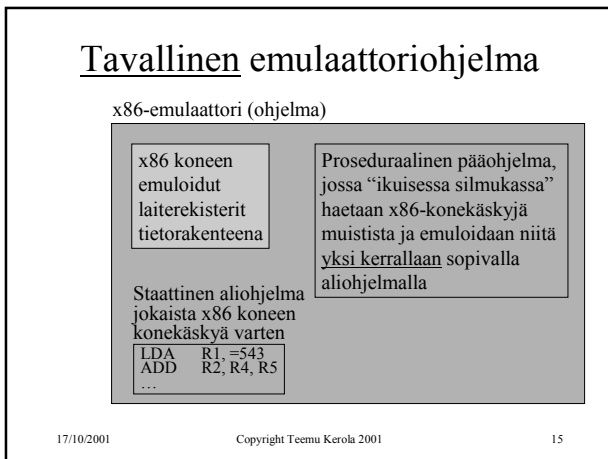

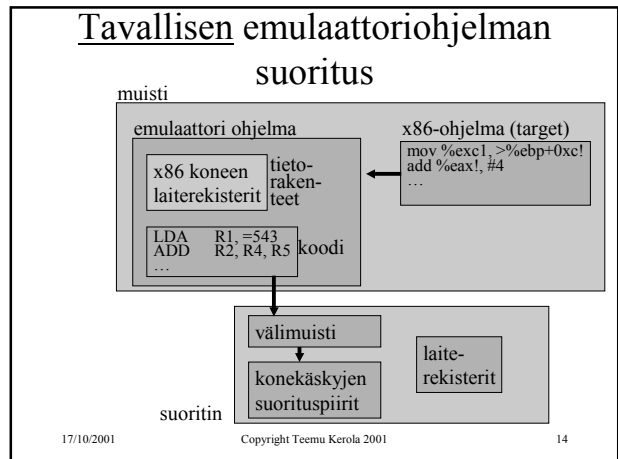

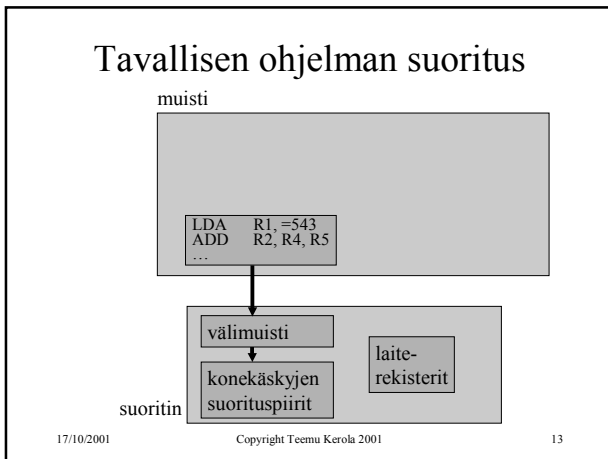

## General Architecture (contd)

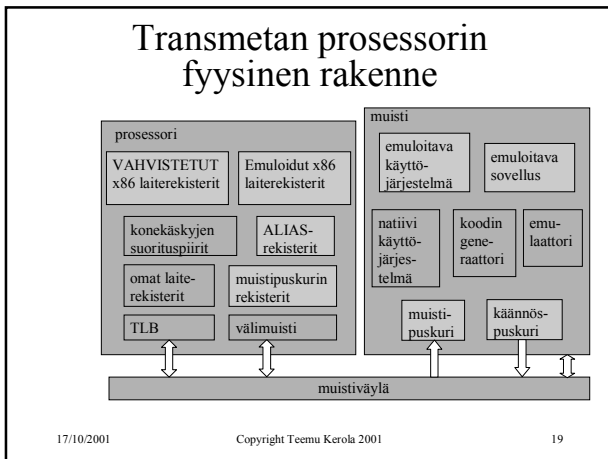

- RISC instruction set
  - explicitly parallel code (VLIW)
  - *commit* instruction supports emulation
    - commits emulated processor and memory state
    - use when coherent target processor (Intel) state!
  - *rollback* instruction (?) supports emulation
    - some or all of it can be in emulator code
    - recover latest committed emulated target register state
    - delete uncommitted writes from store buffer
    - retranslate emulation code for precise state changes
      - *commit* now after every emulated instruction?
  - *prot* instruction for alias detection

### What Will Transmeta do with Crusoe?

- Optimize for speed or size?
  - Small size => cheaper, less power
- Someone else will manufacture chips and compete with Intel?
  - IBM TM3200, TM5400, ..., TM5600 low power  
TM5800 high speed
- Someone else will use the chips to make products to compete with Intel-based products
  - NEC, Fujitsu, Sony, ...
- Midori Linux
  - Open Source project for delivering system software on small devices
    - Gateway, Hitachi, FIC
