#### Motivational Example

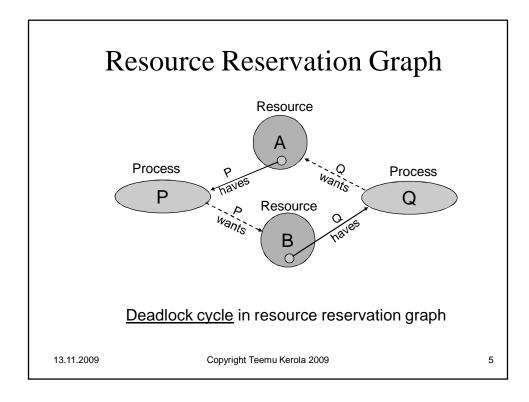

- New possible laptop for CS dept use
  - Lenovo 400, dual-core, Intel Centrino 2 technology
  - Ubuntu Linux 8.10
- Wakeup from suspend/hibernation, freezes often http://ubuntuforums.org/showthread.php?t=959712
- Read, study, experiment some 15 hours?
  - No network?, at home/work?, various units?, ...., ???
  - Problem with Gnome desktop, not with KDE, ..., ???
- Could two processors cause it?
  - Shut down one processor during hibernation/wakeup
  - Wakeup works fine now
- Same problem with many new laptops running Linux
  - All new laptops with Intel Centrino 2 with same Linux driver?
- Concurrency problem in display driver startup?
  - Bug not found yet, use 1-cpu work-around

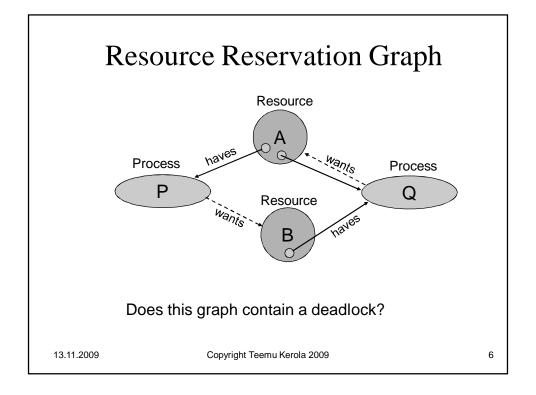

- Bug not tound yet, use 1-epu work a semi-http://git.kemel.org/?p=linux/kernel/git/torvalds/linux-2.6.git;a=commitdiff;h=70740d6c93030b339b4ad17fd58ee135dfc13913 (search "i915\_enable\_vblank"...)

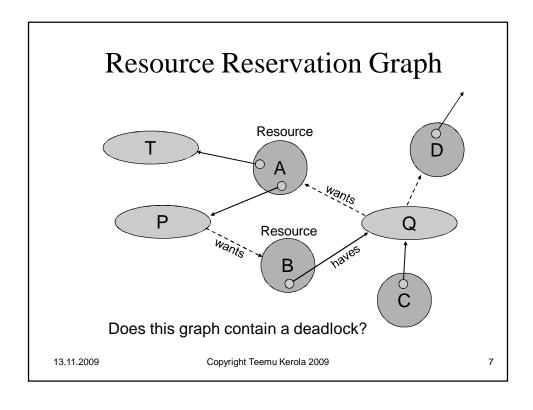

13.11.2009 Copyright Teemu Kerola 2009

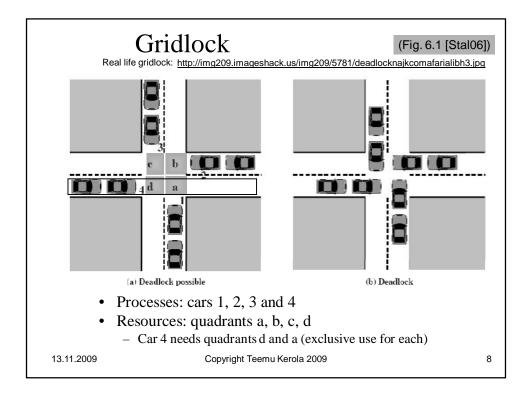

# Consequences

- The processes do not advance
  - Cars do not move
- Resources remain reserved
  - Cpu? Street quadrant?
  - Memory? I/O-devices?
  - Logical resources (semaphores, critical sections, ...)?
- The computation fails
  - Execution never finishes?
    - One application?
  - The system crashes? Traffic flow becomes zero?

13.11.2009

Copyright Teemu Kerola 2009

9

#### Resources

- Reusable resources
  - Limited number or amount
  - Wait for it, allocate it, deallocate (free) it
  - Memory, buffer space, intersection quadrant
  - Critical section code segment execution
  - **–** ...
- Consumable resources
  - Unlimited number or amount
  - Created and consumed
  - Someone may create it, wait for it, destroy it
  - Message, interrupt, <u>turn</u> for critical section

- ...

Copyright Teemu Kerola 2009

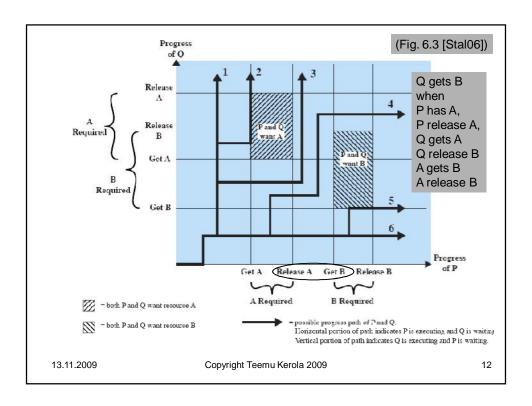

10

Lecture 5: Deadlocks 5

uudelleenkäytettävä resurssi

kulutettava resurssi

#### **Definitions**

Deadlock

lukkiintuminen

- Eternal wait in blocked state
- Does not block processor (unless one resource <u>is</u> processor)
- Livelock

"elolukko"

- Two or more processes continuously change their state (execute/wait) as response to the other process(es), but never advance to real work
- E.g., ping-pong "you first no, you first ..."
  - two processes alternate offering the turn to each other no useful work is started
- Consumes processor time
- Starvation

nälkiintyminen

- the process will never get its turn
- E.g., in ready-to-run queue, but never scheduled

13.11.2009 Copyright Teemu Kerola 2009

13

#### **Deadlock Problems**

- How to know if deadlock exists?
  - How to <u>locate</u> deadlocked processes?
- How to prevent deadlocks?
- How to know if deadlock might occur?
- How to break deadlocks?
  - Without too much damage?
  - Automatically?
- How to <u>prove</u> that your solution is free of deadlocks?

13.11.2009

Copyright Teemu Kerola 2009

14

### Good Deadlock Solution

- Prevents deadlocks in advance, or detects them, breaks them, and fixes the system
- Small overhead
- Smallest possible waiting times
- Does not slow down computations when no danger exists
- Does not block <u>unnecessarily</u> any process when the resource wanted is available

13.11.2009

Copyright Teemu Kerola 2009

15

### Conditions for Deadlock (6)

- Three policy conditions
  - S1. Mutual exclusion

Coffman, 1971 yksi käyttäjä

• one user of any resource at a time (not just code)

S2. Hold and wait

pidä ja odota

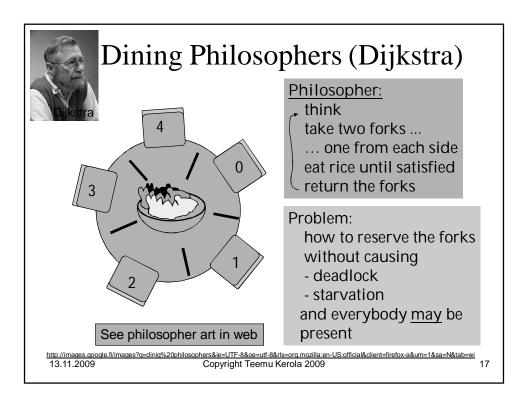

- a process may hold allocated resources while waiting for others
- S3. No preemption

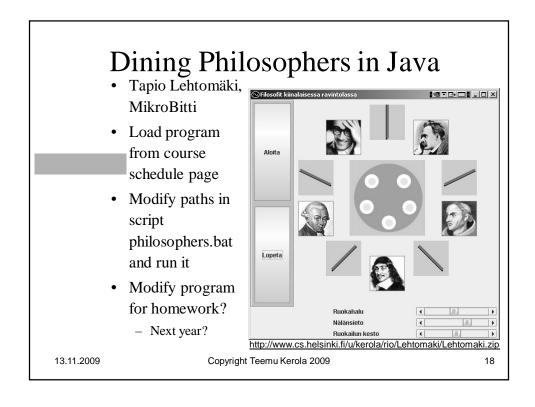

ei keskeytettävissä

- resource can not be forcibly removed from a process holding it
- A dynamic (execution time) condition takes place
  - D1. <u>Circular wait</u>: a closed chain of processes exists, each process holds at least one resource needed by the next process in chain

E.g., slide 5

 $\underline{http://portal.acm.org/citation.cfm?id=356588\&coll=GUIDE\&dl=GUIDE\&CFID=4442763\&CFTOKEN=75849639\&ret=1\#Fulltext=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&CFTOKEN=75849639\&ret=1442763\&ret=1$ 13.11.2009 Copyright Teemu Kerola 2009

```
diningphilosophers */
/* program
                                                  (Fig. 6.12 [Stal06])
semaphore fork [5] = {1}; /* mutex, one at a time */
void philosopher (int i)
    while (true)
                                                  Trivial
         think();
                                    /* left fork */
         wait (fork[i]);
                                                Solution
         wait (fork [(i+1) mod 5]);/* right fork */
         eat();
signal(fork [(i+1) mod 5]);
                                                     #1
         signal(fork[i]);
void main()

    Possible deadlock – not good

           - All 5 grab left fork "at the same time"
 13.11.2009
                                                              19

```

#### **Deadlock Prevention**

- How to prevent deadlock occurrence in advance?
- Deadlock possible only when all 4 conditions are met:

- S1. Mutual exclusion

poissulkemistarve

- S2. Hold and wait

pidä ja odota

- S3. No preemption

ei saa ottaa pois kesken kaiken

- D1. Circular wait

kehäodotus

- Solution: disallow any one of the conditions
  - S1, S2, S3, or D1?
  - Which is possible to disallow?
  - Which is easiest to disallow?

13.11.2009

Copyright Teemu Kerola 2009

21

# Disallow S1 (mutual exclusion)

- Can not do always
  - There are reasons for mutual exclusion!
    - Can not split philosophers fork into 2 resources
- Can do sometimes
  - Too high granularity blocks too much
    - Resource *room* in trivial solution #2
  - Finer granularity allows parallelism
    - Smaller areas, parallel usage, more locks
    - · More administration to manage more locks
    - Too fine granularity may cause too much administration work
  - Normal design approach in data bases, for example
- Get more resources, avoid mutex competition?
  - Buy another fork for each philosopher?

13.11.2009

Copyright Teemu Kerola 2009

22

# Disallow S2 (hold and wait)

- · Request all needed resources at one time
- Wait until all can be granted simultaneously
  - Can lead to starvation
    - Reserve both forks at once (simultaneous wait!)
    - Neighbouring philosophers eat all the time alternating

- Inefficient
  - long wait for resources (to be used much later?)

 worst case reservation (long wait period for resources which are possibly needed - who knows?)

- Difficult/impossible to implement?
  - advance knowledge: resources of all possible execution paths of all related modules ...

13.11.2009

Copyright Teemu Kerola 2009

23

# Disallow S3 (no preemption)

- · Allow preemption in crisis
- Release of resources => fallback to some earlier state
  - Initial reservation of these resources
  - Fall back to specific checkpoint
  - Checkpoint must have been saved earlier
  - Must know when to fall back!
- OK, if the system has been designed for this
  - Practical, if saving the state is cheap and the chance of deadlock is to be considered
  - Standard procedure for transaction processing
- wait (fork[i]); if "all forks taken" then "remove fork" from philosopher [i⊕1] wait (fork[i⊕1])
  - What will philosopher i⊕1 do now? Think? Eat? Die?

13.11.2009

Copyright Teemu Kerola 2009

24

# Disallow D1 (circular wait)

- Linear ordering of resources
  - Make reservations in this order only no loops!
- Pessimistic approach prevent "loops" in advance
  - Advance knowledge of resource requirements needed
  - Reserve <u>all at once</u> in given order
  - Prepare for "worst case" behavior

Forks in global ascending order philosophers 0, 1, 2, 3:
wait (fork[i]);
wait (fork[i+1]);

- Optimistic approach worry only at the last moment
  - Reservation dynamically as needed (but <u>in order</u>)
  - Reservation conflict => restart from some earlier stage
    - Must have earlier state saved somewhere

13.11.2009

Copyright Teemu Kerola 2009

25

#### Deadlock Detection and Recovery (4)

- Let the system run until deadlock problem occurs
  - "Detect deadlock existance"
  - "Locate deadlock and fix the system"
- Detection is not trivial:
  - Blocked group of processes is deadlocked? or
  - Blocked group is just waiting for an external event?
- Recovery
  - Detection is first needed
  - Fallback to a previous state (does it exist?)
  - Killing one or more members of the deadlocked group
    - Must be able to do it without overall system damage
- Needed: information about resource allocation
  - In a form suitable for deadlock detection!

13.11.2009

Copyright Teemu Kerola 2009

26

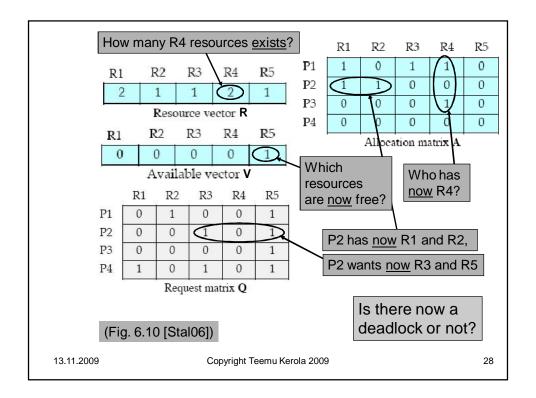

#### **Resource Allocation**

- Processes Pi ∈ P1..Pn
- Resources (or objects) Rj ∈ R1..Rm
- · Number of resources of type Rj
  - total amount of resources  $\mathbf{R} = (r_1, ..., r_m)$
  - currently <u>free</u> resources  $\mathbf{V} = (v_1, ..., v_m)$
- · Allocated resources (allocation matrix)
  - $\mathbf{A} = [a_{ij}]$ , "process Pi has  $a_{ij}$  units of resource Rj"
- Outstanding requests (<u>request</u> matrix)
  - $Q = [q_{ij}]$ , "process Pi requests  $q_{ij}$  units of resource Rj"

13.11.2009

Copyright Teemu Kerola 2009

27

### Deadlock Detection (Dijkstra) (4)

- 1. Find a (any) process that <u>could</u> terminate
  - <u>All</u> of its <u>current</u> resource requests <u>can</u> be satisfied

- 2. Assume now that
  - a. This process terminates, and
  - b. It releases all of its resources
- 3. Repeat 1&2 until can not find any more such processes
- 4. If any processes still exist, they are deadlocked
  - a. They all each need something
  - b. The process holding that something is <u>waiting</u> for something else
    - That process can not advance and release it

13.11.2009

Copyright Teemu Kerola 2009

20

#### Deadlock Detection Algorithm (DDA)

- DL1. [Remove the processes with no resources] Mark all processes with null rows in **A**.
- DL2. [Initialize counters for available objects] Initialize a working vector  $\mathbf{W} = \mathbf{V}$
- DL3. [Search for a process Pi which could get all resources it requires]

Search for an unmarked row i such that

 $q_{ij} \le w_j \qquad j = 1..n$ 

If none is found terminate the algorithm.

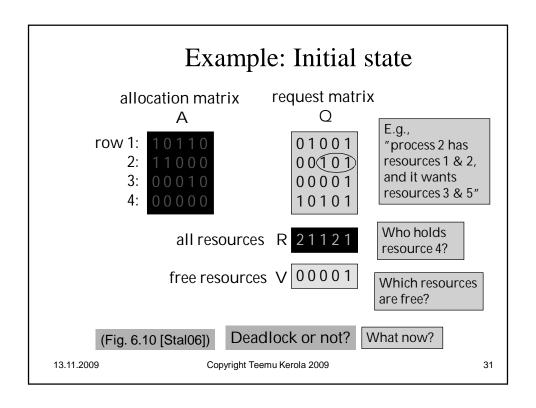

DL4. [Increase **W** with the resources of the chosen process] Set  $\mathbf{W} = \mathbf{W} + A_{j^*}$  i.e.  $w_j = w_j + a_{ij}$  when j = 1..nMark process Pi and return to step DL3.

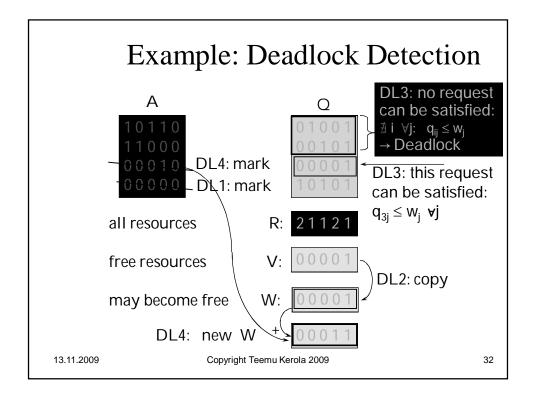

When the algorithm terminates, unmarked processes correspond to deadlocked processes. Why?

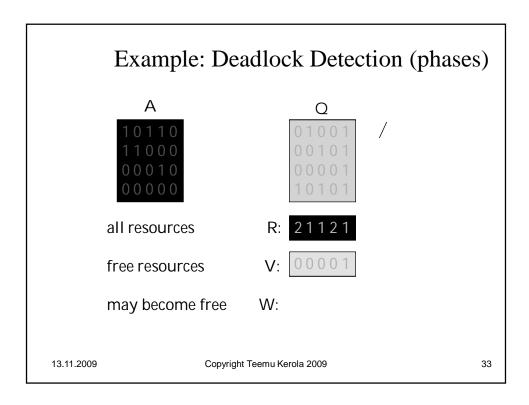

13.11.2009

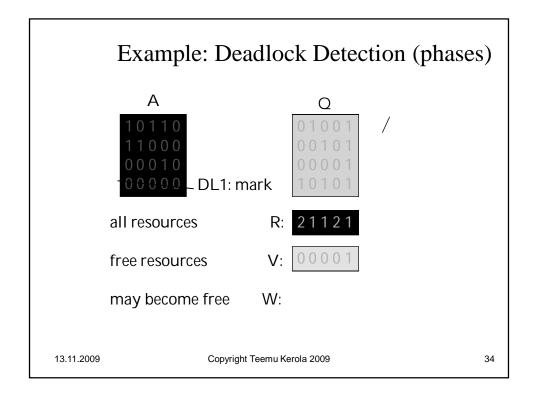

Copyright Teemu Kerola 2009

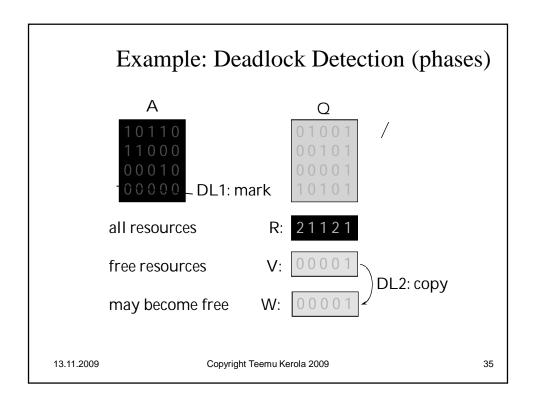

30

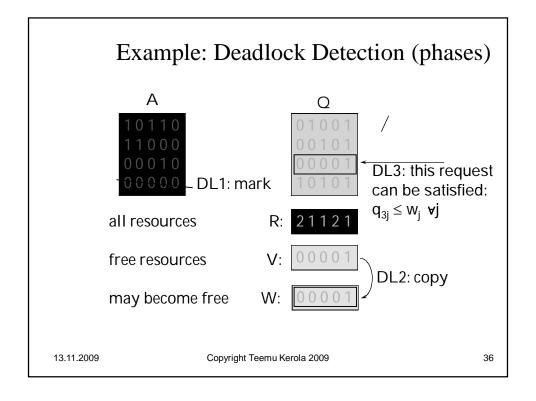

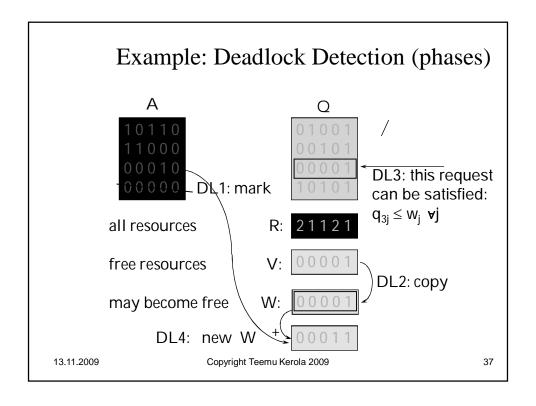

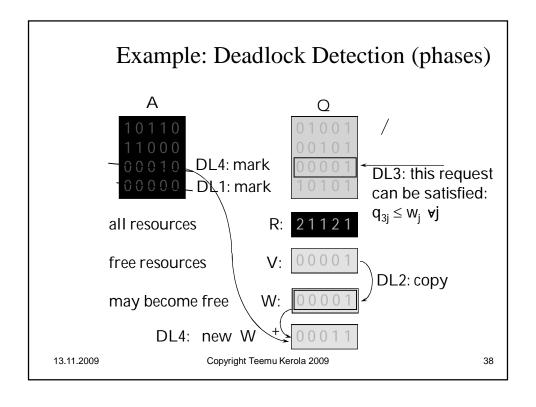

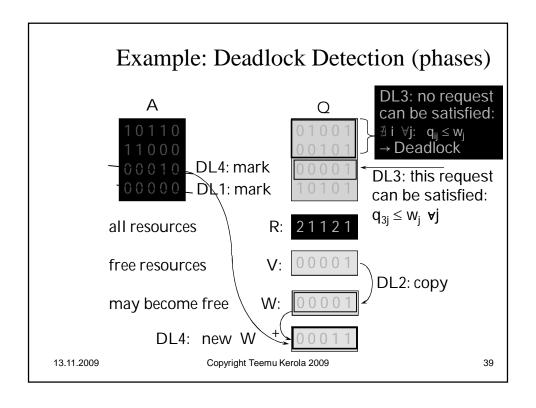

# **Example: Breaking Deadlocks**

- Processes P1 and P2 are in deadlock
  - What next?
- Abort P1 and P2
  - Most common solution
- Rollback P1 and P2 to previous safe state, and try again
  - Rollback states <u>must exist</u>
  - May deadlock again (or may not!)
- Abort P1 because it is less important
  - Must have some basis for selection
  - Who makes the decision? Automatic?
- Preempt R3 from P1
  - Must be <u>able to preempt</u> (easy if R3 is CPU?)
  - Must know what to preempt from whom
  - <u>How many</u> resources need preemption?

13.11.2009

Copyright Teemu Kerola 2009

40

# Deadlock **Avoidance** with DDA

- Use Dijstra's algorithm to avoid deadlocks in advance?
- Banker's Algorithm

Pankkiirin algoritmi

- Originally for one resource (money)
- Why "Banker's"?
  - "Ensure that a bank never allocates its available cash so that it can no longer satisfy the needs of all its customers"

13.11.2009

Copyright Teemu Kerola 2009

41

# Banker's Algorithm (6)

- Keep state information on resources <u>allocated to</u> each process
- Keep state information on number of resources each process <u>might still allocate</u>
- For <u>each</u> resource allocation, <u>first</u> find an ordering which allows processes to terminate, if that allocation is made
  - Assume that allocation is made and then use DDA to find out if the system remains in a safe state even in the worst case
  - If deadlock is possible, reject resource request
  - If deadlock is not possible, grant resource request

13.11.2009

Copyright Teemu Kerola 2009

42

# Deadlock Avoidance with Banker's Algorithm (6)

Matrices as before, and some more

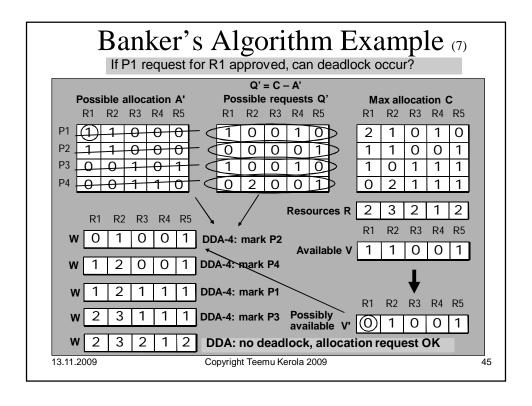

- For each process: the <u>maximum needs</u> of resources  $-\mathbf{C} = [c_{ij}]$ , "Pi may request  $c_{ij}$  units of Rj"
- The current hypothesis of resources in use  $-\mathbf{A'} = [a'_{ii}]$ , "if this allocation is made,

Pi would have  $a_{ii}$  units of Rj"

- The current hypothesis of future maximum demands
  - $\mathbf{Q'} = [q'_{ij}]$ , "Pi could still request  $q'_{ij}$  units of Rj"  $\mathbf{Q'} = \mathbf{C} - \mathbf{A'}$
- Apply DDA to A' and Q'
  - If no deadlock possible, grant resource request

13.11.2009 Copyright Teemu Kerola 2009 43

#### Banker's Algorithm Example **Allocation A** Requests Q **Max allocation C** R1 R2 R3 R4 R5 R2 R3 R4 R5 R2 R3 R4 R5 0 0 0 0 0 0 0 0 1 0 P2 0 0 0 0 0 0 1 1 0 0 1 P3 0 1 1 1 0 1 0 0 0 0 0 1 1 1 1 2 1 0 0 0 0 1 Resources R 2 3 2 1 2 R4 R2 1 0 0 Available V 1 (Fig. 16.11, Bacon, Concurrent Systems, 1993) P1 requests R1. Is request granted? Could system deadlock, if R1 is granted? 13.11.2009 Copyright Teemu Kerola 2009 44

### Avoidance: Problems

- Each allocation: a considerable overhead
  - Run Banker's algorithm for 20 processes and 100 resources?
- Knowledge of maximum needs
  - In advance?
    - An educated guess? Worst case?
  - Dynamically?
    - · Even more overhead
- A safe allocation does not always exist
  - An unsafe state does not always lead to deadlock
  - You may want to take a risk!

Another Banker's Algorithm example: B. Gray, Univ. of Idaho http://www.if.uidaho.edu/~bgray/classes/cs341/doc/banker.html

13.11.2009

46 Copyright Teemu Kerola 2009

# **Summary**

- Difficult real problem
- Can detect deadlocks

Dijkstra's DDA

- Need specific data on resource usage
- Difficult to break deadlocks
  - How will killing processes affect the system?
- Can prevent deadlocks

Bankers

- Prevent any one of those four conditions
  - E.g., reserve resources always in given order
- Can analyze system at resource reservation time to see whether deadlock might result
  - Complex and expensive

13.11.2009
