C-Brahms Research Group

Content-Based Retrieval and Analysis of Harmony and other Music Structures

1. Content-Based Music Retrieval

Content-Based Music (Information) Retrieval, CBMR (at times referred to as MIR), is a research topic that has been studied rather extensively during the last half a decade. One of its famous instances is the so-called "query by humming" or WYHIWYG (What You Hum Is What You Get) application. Given a large database of music, the task is to find those pieces of music that contain excerpts mostly resembling (in a musical way) the hummed query.

The C-BRAHMS project aims at designing and developing efficient methods for computational problems arising from music comparison, retrieval, and analysis. Particularly, the project concentrates on retrieving polyphonic music in large scale music databases containing symbolically encoded music. The project uses the findings in musicology and music psychology to achieve musically meaningful methods and results. Moreover, all the project output is planned to be exhibited in a freely available (under the GNU General Public License) query engine.

C-Brahms Group

The C-BRAHMS project was formally established in January, 2002. C-BRAHMS is a subproject to Combinatorial Pattern Matching and Information Retrieval (CPM) within the From Data to Knowledge (FDK) research unit jointly hosted by the Department of Computer Science at the University of Helsinki, and the Laboratory of Computer and Information Science at Helsinki University of Technology. FDK has been selected as one of the centres of excellence by the Academy of Finland for the period 2002-2007.

The group collaborates with several researchers and research groups abroad: the Intelligent Sound and Music Systems group at City University, London (headed by Dr. Geraint Wiggins), the Algorithm Design Group at King's College, London (headed by Prof. Costas Iliopoulos), for instance.

1. Problem setting

The task is to find occurrences of a pattern (1a) in a polyphonic source (1b). In this example two transposed occurrences are given in green colour. The former is a complete match, the latter a partial match with one error (the note given in red colour).

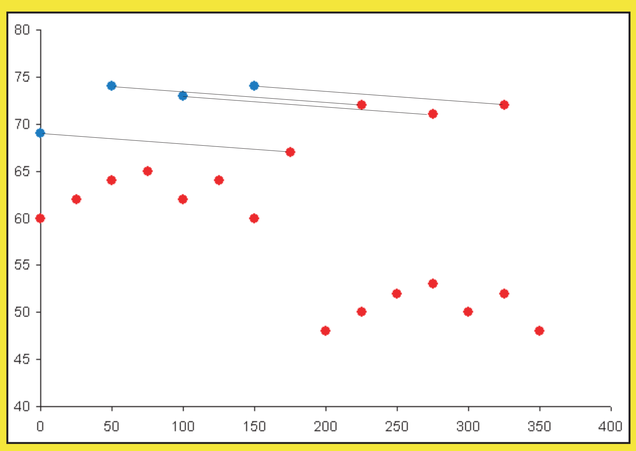
Symbolic musical data may be represented e.g. as strings or as geometric point sets. In the C-BRAHMS group, algorithms for both representations have been developed.

1a. Pattern

1b. Score

2. Geometric representation

In geometric representation both pattern and source are presented as points in a multidimensional space (e.g. time-pitch space below). In the example below, pattern is represented with blue colour and source with red colour.
For example SIA(M)E algorithm (Wiggins et al. 2002) calculates difference vectors between each source point and pattern point, sorts the vectors, and calculates the frequency of all such difference vectors. For instance, there is a complete match, if the frequency of some difference vector equals the number of points in the pattern.
Algorithms P1 and P2 (Ukkonen et al. 2003) are applicable for the same problem with somewhat better performances.



3. String representation

The conventional string matching techniques can be used in finding occurrences of the pattern separately from each track (as in Fig. 1b).

In polyphonic music, however, the occurrences may be distributed across the tracks. We have developed string matching methods for finding such occurrences as well (Lemström 2000, Lemström and Tarhio 2003, and Lemström and Mäkinen 2003).

3a. Pattern

```
a5 d6 c#6 d6
69 74 73 74
```

3b. Source (first bar)

```
Track 1:  c5 d5 e5 f5 d5 e5 c5 g5 -  c6 -  b5 -  c6 -
          60 62 64 65 62 64 60 67 -  72 -  71 -  72 -
Track 2:  -  -  -  -  -  -  -  -  c4 d4 e4 f4 d4 e4 c4
          -  -  -  -  -  -  -  -  48 50 52 53 50 52 48
```

3. Summary

* New state of the art geometric polyphonic algorithms
* Also fast bit-parallel polyphonic string matching based algorithms
* Demo search engine at http://www.cs.helsinki.fi/group/cbrahms
