582606 Introduction to bioinformatics

Autumn 2007
Esa Pitkänen
Master's Degree Programme in Bioinformatics (MBI)
Department of Computer Science, University of Helsinki
http://www.cs.helsinki.fi/mbi/courses/07-08/itb/
Administrative issues

- Master level course
- Obligatory course in the Master’s Degree Programme in Bioinformatics
- 4 credits
- Prerequisites: basic mathematical skills
- Lectures: Tuesdays and Fridays 14-16 in Exactum C222
- Exercises: Wednesday 14-16 in Exactum C221
Teachers

- Esa Pitkänen, Department of Computer Science, University of Helsinki
- Prof. Elja Arjas, Department of Mathematics and Statistics, University of Helsinki
- Prof. Samuel Kaski, Laboratory of Computer and Information Science, Helsinki University of Technology
- Lauri Eronen, Department of Computer Science, University of Helsinki
How to enrol for the course?

- Use the registration system of the Computer Science department: https://ilmo.cs.helsinki.fi

- If you don’t have a student number or Finnish id yet, don’t worry: attend the lectures and exercises, and register when you have the id
How to successfully pass the course?

- You can get a maximum of 60 points
  - Course exam: maximum of 50 points
  - Exercises: maximum of 10 points
    - 0% completed assignments gives you 0 points, 80% gives 10 points, the rest by linear interpolation
    - “A completed assignment” means that you are willing to present your solution to the class in the exercise session
- Course will be graded on the scale 0-5
  - To get the lowest passing grade 1/5, you need to have at least 30 points
- Course exam: Wednesday 17.10. at 16.00-19.00 in A111
Course material

- Available at Kumpula and Viikki science libraries; book stores (Amazon.com ~$56, Akateeminen kirjakauppa ~75€, Yliopistokirjakauppa 71€)

- It is recommended that you have access to the course book!

- Slides for some lectures will be available on the course web page (copies in room C127)
Additional material

• Check the course web site

• N. C. Jones & P. A. Pevzner: An introduction to bioinformatics algorithms

• Alberts et al.: Molecular biology of the cell

• Lodish et al.: Molecular cell biology
Course contents

• Biological background (book chapter 1)
• Probability calculus ( chapters 2 and 3)
• Sequence alignment (chapter 6)
• Rapid alignment methods: FASTA and BLAST (chapter 7)
• Phylogenetic trees (chapter 12)
• Expression data analysis (chapter 11)
Master's Degree Programme in Bioinformatics (MBI)

- Two-year MSc programme
  - You need to have your Bachelor’s degree ready by August 2008

www.cs.helsinki.fi/mbi
MBI programme

- MBI educates bioinformatics professionals who
  - Specialise in computational and statistical methods
  - Work in R&D tasks in biology and medicine
MBI programme

- Two-year masters programme (120 cr)
- Offered jointly by the University of Helsinki (HY) and Helsinki University of Technology (TKK)
- Began in 2006 as a national programme, 2007 international admission
- Students 8 + 7 (2006 + 2007)
MBI programme organizers

Department of Computer Science, Department of Mathematics and Statistics, HY

Laboratory of Computer and Information Science, TKK

Faculty of Medicine, HY

Faculty of Biosciences, Faculty of Agriculture and Forestry, HY
Bioinformatics courses at the University of Helsinki

1. Department of Computer Science

- Practical course in biodatabases (II period): techniques for accessing and integrating data in biology databases.
- Biological sequence analysis (III period): basic probabilistic methods for modelling and analysis of biological sequences.
- Seminar: Regulatory networks (I & II periods)
- Seminar: Management of biological databases (III & IV periods)
Bioinformatics courses at the University of Helsinki

Department of Mathematics and Statistics

- Statistical methods in genetic epidemiology and gene mapping (I period)
- Mathematical modelling (I & II periods)
- Practical course on phylogenetic analysis (IV period): recommended to take also Biological sequence analysis
- Adaptive dynamics (III & IV periods)
Bioinformatics courses at Helsinki University of Technology

Laboratory of Computer and Information Science

- Computational genomics (I & II periods): Algorithms and models for biological sequences and genomics
- Signal processing in neuroinformatics (I and II periods): overview of some of the main biomedical signal processing techniques
- High-throughput bioinformatics (III and IV periods): computational and statistical methods for analyzing modern high-throughput biological data
- Image analysis in neuroinformatics (III and IV periods): biomedical image processing techniques
Biology for methodological scientists (8 cr)

- Course organized by the Faculties of Bioscience and Medicine for the MBI programme
- Introduction to basic concepts of microarrays, medical genetics and developmental biology
- Book exam in I period (2 cr)
- Organized in three lectured modules, 2 cr each
- Each module has an individual registration so you can participate even if you missed the first module
Bioinformatics courses

- Visit the website of Master's Degree Programme in Bioinformatics for up-to-date course lists:
  http://www.cs.helsinki.fi/mbi
An introduction to bioinformatics
What is bioinformatics?

- Solving biological problems with computation?
- Collecting, storing and analysing biological data?
- Informatics - library science?
What is bioinformatics?

- Bioinformatics, *n.* The science of information and information flow in biological systems, esp. of the use of computational methods in genetics and genomics. (Oxford English Dictionary)

- "The mathematical, statistical and computing methods that aim to solve biological problems using DNA and amino acid sequences and related information."
  -- Fredj Tekaia

- "I do not think all biological computing is bioinformatics, e.g. mathematical modelling is not bioinformatics, even when connected with biology-related problems. In my opinion, bioinformatics has to do with management and the subsequent use of biological information, particular genetic information."
  -- Richard Durbin
What is not bioinformatics?

- Biologically-inspired computation, e.g., genetic algorithms and neural networks
- However, application of neural networks to solve some biological problem, could be called bioinformatics
- What about DNA computing?
Related concepts

- Computational biology
  - Application of computing to biology (broad definition)
  - Often used interchangeably with bioinformatics

- Biometry: the statistical analysis of biological data

- Biophysics: "an interdisciplinary field which applies techniques from the physical sciences to understanding biological structure and function" -- British Biophysical Society

- Mathematical biology “tackles biological problems, but the methods it uses to tackle them need not be numerical and need not be implemented in software or hardware.” -- Damian Counsell
Related concepts

• Systems biology
  – “biology of networks”
  – integrating different levels of information to understand how biological systems work

• Computational systems biology

*Overview of metabolic pathways in KEGG database, www.genome.jp/kegg/*
Why is bioinformatics important?

- New measurement techniques produce huge quantities of biological data
  - Advanced data analysis methods are needed to make sense of the data
  - Typical data sources produce noisy data with a lot of missing values
- Paradigm shift in biology to utilise bioinformatics in research
- To give you a glimpse of a typical situation in bioinformatics…
DNA microarray data

Outi Monni, Biochip Center, Biomedicum
Biological background

- Molecular Biology Primer: www.bioalgorithms.info
Today’s program

• Biological background (book chapter 1)
  – Molecular primer continues
  – Recap of the most important material with respect to the course
• A word or two about exercises and the exam
• Note that the lecture on 9.10. is moved to room ExactumB222
Course contents (18.9.)

- Biological background (book chapter 1)
- Probability calculus (chapters 2 and 3)
- **Sequence alignment (chapter 6)**
  - This week (18.9. and 21.9.)
- Rapid alignment methods: FASTA and BLAST (chapter 7)
  - Next week (25.9. and 28.9.)
- Phylogenetic trees (chapter 12)
- Expression data analysis (chapter 11)
Sequence Alignment (chapter 6)

- The biological problem
- Global alignment
- Local alignment
- Multiple alignment
Background: comparative genomics

- Basic question in biology: *what properties are shared among organisms?*
- Genome sequencing allows comparison of organisms at DNA and protein levels
- Comparisons can be used to
  - Find evolutionary relationships between organisms
  - Identify functionally conserved sequences
  - Identify corresponding genes in human and model organisms: develop models for human diseases
Homologs

- Two genes $g_B$ and $g_C$ evolved from the same ancestor gene $g_A$ are called *homologs*

  \[ g_A = agtgccgtaagtgccgtttc \]

  \[ g_B = agtgccgttaagttgtacgtc \]

  \[ g_C = ctgactgtttgtggtttc \]

- Homologs usually exhibit conserved functions

- Close evolutionary relationship => expect a high number of homologs
Sequence similarity

- Intuitively, similarity of two sequences refers to the degree of match between corresponding positions in sequence.

\[
\text{agtgccgtaaagttgtacgtc}
\]

\[
\text{ctgactgttttgtggttc}
\]

- What about sequences that differ in length?
Similarity vs homology

Sequence similarity is not sequence homology

- If the two sequences \( g_B \) and \( g_C \) have accumulated enough mutations, the similarity between them is likely to be low.

Homology is more difficult to detect over greater evolutionary distances.
Similarity vs homology (2)

- Sequence similarity can occur by chance
  - *Similarity does not imply homology*

- Consider comparing two short sequences against each other
Orthologs and paralogs

- We distinguish between two types of homology
  - Orthologs: homologs from two different species, separated by a *speciation* event
  - Paralogs: homologs within a species, separated by a *gene duplication* event
Orthologs and paralogs (2)

- Orthologs typically retain the original function.
- In paralogs, one copy is free to mutate and acquire new function (no selective pressure).
Paralogy example: hemoglobin

- Hemoglobin is a protein complex which transports oxygen.
- In humans, hemoglobin consists of four protein subunits and four non-protein heme groups.

Sickle cell diseases are caused by mutations in hemoglobin genes.

Hemoglobin A, [view structure](http://www.rcsb.org/pdb/explore.do?structureId=1GZX)

[Image of sickle cells](http://en.wikipedia.org/wiki/Image:Sicklecells.jpg)
Paralogy example: hemoglobin

• In adults, three types are normally present
  – Hemoglobin A: 2 alpha and 2 beta subunits
  – Hemoglobin A2: 2 alpha and 2 delta subunits
  – Hemoglobin F: 2 alpha and 2 gamma subunits

• Each type of subunit (alpha, beta, gamma, delta) is encoded by a separate gene

Hemoglobin A,
www.rcsb.org/pdb/explore.do?structureId=1GZX
Paralogy example: hemoglobin

- The subunit genes are paralogs of each other, i.e., they have a common ancestor gene
  - Find human hemoglobin alpha, beta, gamma and delta
  - Compare sequences

Hemoglobin A, www.rcsb.org/pdb/explore.do?structureId=1GZX
Orthology example: insulin

- The genes coding for insulin in human (*Homo sapiens*) and mouse (*Mus musculus*) are orthologs:
  - They have a common ancestor gene in the ancestor species of human and mouse
  - Demonstration in lecture: find insulin orthologs from human and mouse in NCBI sequence databases
Sequence alignment

- Alignment specifies which positions in two sequences match

```
acgtctag    acgtctag    acgtctag
||         ||      ||
actctag-    -actctag  ac-tctag
```

- 2 matches
- 5 mismatches
- 1 not aligned

- 5 matches
- 2 mismatches
- 1 not aligned

- 7 matches
- 0 mismatches
- 1 not aligned
Mutations: Insertions, deletions and substitutions

**Indel**: insertion or deletion of a base with respect to the ancestor sequence

```
acgtctag
```

**Mismatch**: substitution (point mutation) of a single base

```
actctag
```

- Insertions and/or deletions are called *indels*
  - *We can’t tell whether the ancestor sequence had a base or not at indel position*
Problems

- What sorts of alignments should be considered?
- How to score alignments?
- How to find optimal or good scoring alignments?
- How to evaluate the statistical significance of scores?

In this course, we discuss each of these problems briefly.

Course *Biological sequence analysis* tackles all four in-depth.
Sequence Alignment (chapter 6)

- The biological problem
- *Global alignment*
- Local alignment
- Multiple alignment
Global alignment

- Problem: find optimal scoring alignment between two sequences (Needleman & Wunsch 1970)
- Every position in both sequences is included in the alignment
- We give score for each position in alignment
  - Identity (match) +1
  - Substitution (mismatch) -µ
  - Indel -δ
- Total score: sum of position scores

\[ S(\text{WHAT}/\text{WH-Y}) = 1 + 1 - \delta - \mu \]
Dynamic programming

- How to find the optimal alignment?
- We use previous solutions for optimal alignments of smaller subsequences
- This general approach is known as dynamic programming
Introduction to dynamic programming: the money change problem

- Suppose you buy a pen for 4.23€ and pay for with a 5€ note
- You get 77 cents in change – what coins is the cashier going to give you if he or she tries to minimise the number of coins?
- The usual algorithm: start with largest coin (denominator), proceed to smaller coins until no change is left:
  - 50, 20, 5 and 2 cents
- This greedy algorithm is *incorrect*, in the sense that it does not always give you the correct answer
The money change problem

- How else to compute the change?
- We could consider all possible ways to reduce the amount of change
- Suppose we have 77 cents change, and the following coins: 50, 20, 5 cents
- We can compute the change with recursion
- Figure shows the recursion tree for the example

- Many values are computed more than once!
- This leads to a correct but very inefficient algorithm
The money change problem

- We can speed the computation up by solving the change problem for all $i \leq n$
  - Example: solve the problem for 9 cents with available coins being 1, 2 and 5 cents
- Solve the problem in steps, first for 1 cent, then 2 cents, and so on
- In each step, utilise the solutions from the previous steps
The money change problem

- Algorithm runs in time proportional to $Md$, where $M$ is the amount of change and $d$ is the number of coin types
- The same technique of storing solutions of subproblems can be utilised in aligning sequences
Representing alignments and scores

Alignments can be represented in the following tabular form.

Each alignment corresponds to a path through the table.

<table>
<thead>
<tr>
<th></th>
<th>-</th>
<th>W</th>
<th>H</th>
<th>A</th>
<th>T</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>W</td>
<td></td>
<td></td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>H</td>
<td>X</td>
<td></td>
<td></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td>Y</td>
<td></td>
<td></td>
<td></td>
<td>X</td>
<td></td>
</tr>
</tbody>
</table>

WHAT

WH-Y
Representing alignments and scores

Global alignment score $S_{3,4} = 2-\delta-\mu$
Consider the alignment process at shaded square.

**Case 1.** Align H against H (match or substitution).

**Case 2.** Align H in WHY against – (indel) in WHAT.

**Case 3.** Align H in WHAT against – (indel) in WHY.
### Filling the alignment matrix (2)

<table>
<thead>
<tr>
<th></th>
<th>-</th>
<th>W</th>
<th>H</th>
<th>A</th>
<th>T</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>W</td>
<td>Case 1</td>
<td>Case 2</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>H</td>
<td>Case 3</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Y</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Scoring the alternatives.

**Case 1.** \( S_{2,2} = S_{1,1} + s(2, 2) \)

**Case 2.** \( S_{2,2} = S_{1,2} - \delta \)

**Case 3.** \( S_{2,2} = S_{2,1} - \delta \)

\( s(i, j) = 1 \) for matching positions,
\( s(i, j) = -\mu \) for substitutions.

Choose the case (path) that yields the maximum score.

Keep track of path choices.
Global alignment: formal development

$$A = a_1a_2a_3\ldots a_n,$$
$$B = b_1b_2b_3\ldots b_m$$

\[
\begin{array}{c c c c c}
    & b_1 & b_2 & b_3 & b_4 \\
\hline
0 & - & b_1 & b_2 & b_3 & b_4 \\
1 & a_1 & - & a_2 & a_3 \\
2 & a_2 & & & \\
3 & a_3 & & & \\
\end{array}
\]

Any alignment can be written as a unique path through the matrix.

Score for aligning A and B up to positions i and j:

$$S_{i,j} = S(a_1a_2a_3\ldots a_i, b_1b_2b_3\ldots b_j)$$
Scoring partial alignments

Alignment of $A = a_1 a_2 a_3 \ldots a_n$ with $B = b_1 b_2 b_3 \ldots b_m$ can end in three ways

- Case 1: $(a_1 a_2 \ldots a_{i-1}) a_i$
  $(b_1 b_2 \ldots b_{j-1}) b_j$

- Case 2: $(a_1 a_2 \ldots a_{i-1}) a_i$
  $(b_1 b_2 \ldots b_j) -$  

- Case 3: $(a_1 a_2 \ldots a_i) -$  
  $(b_1 b_2 \ldots b_{j-1}) b_j$
Scoring alignments

Scores for each case:

- Case 1: \((a_1a_2...a_{i-1}) a_i (b_1b_2...b_{j-1}) b_j\)

  \[s(a_i, b_j) = \begin{cases} 
  +1 & \text{if } a_i = b_j \\
  -\mu & \text{otherwise}
  \end{cases}\]

- Case 2: \((a_1a_2...a_{i-1}) a_i (b_1b_2...b_j) -\)

- Case 3: \((a_1a_2...a_i) - (b_1b_2...b_{j-1}) b_j\)

  \[s(a_i, -) = s(-, b_j) = -\delta\]
Scoring alignments (2)

• First row and first column correspond to initial alignment against indels:
  \[ S(i, 0) = -i \delta \]
  \[ S(0, j) = -j \delta \]

• Optimal global alignment score \( S(A, B) = S_{n,m} \)

\[
\begin{array}{c|ccccc}
0 & 0 & 1 & 2 & 3 & 4 \\
\hline
0 & - & b_1 & b_2 & b_3 & b_4 \\
1 & a_1 & -\delta & & & \\
2 & a_2 & -2\delta & & & \\
3 & a_3 & -3\delta & & & \\
\end{array}
\]
Algorithm for global alignment

Input sequences $A$, $B$, $n = |A|$, $m = |B|$

Set $S_{i,0} := -\delta i$ for all $i$

Set $S_{0,j} := -\delta j$ for all $j$

for $i := 1$ to $n$

   for $j := 1$ to $m$

      $S_{i,j} := \max\{S_{i-1,j} - \delta, S_{i-1,j-1} + s(a_i, b_j), S_{i,j-1} - \delta\}$

end

end

Algorithm takes $O(nm)$ time and space.
Global alignment: example

\[ \mu = 1 \]
\[ \delta = 2 \]

\[
\begin{array}{ccccccc}
  & - & T & G & G & T & G \\
- & 0 & -2 & -4 & -6 & -8 & -10 \\
A & -2 &   &   &   &   &   \\
T & -4 &   &   &   &   &   \\
C & -6 &   &   &   &   &   \\
G & -8 &   &   &   &   &   \\
T & -10 &   &   &   &   & ?
\end{array}
\]
Global alignment: example (2)

\[ \mu = 1 \]
\[ \delta = 2 \]

\[
\begin{array}{c|ccccccc}
 & - & T & G & G & T & G \\
- & 0 & -2 & -4 & -6 & -8 & -10 \\
A & -2 & -1 & -3 & -5 & -7 & -9 \\
T & -4 & -1 & -2 & -4 & -4 & -6 \\
C & -6 & -3 & -2 & -3 & -5 & -5 \\
G & -8 & -5 & -2 & -1 & -3 & -4 \\
T & -10 & -7 & -4 & -3 & 0 & -2 \\
\end{array}
\]
Sequence Alignment (chapter 6)

- The biological problem
- Global alignment
  - Local alignment
- Multiple alignment
Local alignment: rationale

- Otherwise dissimilar proteins may have local regions of similarity
  -> Proteins may share a function

Human bone morphogenic protein receptor type II precursor (left) has a 300 aa region that resembles 291 aa region in TGF-β receptor (right).

The shared function here is protein kinase.
Local alignment: rationale

- Global alignment would be inadequate
- Problem: find the highest scoring *local* alignment between two sequences
- Previous algorithm with minor modifications solves this problem (Smith & Waterman 1981)
From global to local alignment

- Modifications to the global alignment algorithm
  - Look for the highest-scoring path in the alignment matrix (not necessarily through the matrix), or in other words:
  - Allow preceding and trailing indels without penalty
Scoring local alignments

A = a_1a_2a_3...a_n, B = b_1b_2b_3...b_m

Let I and J be intervals (substrings) of A and B, respectively: \( I \subset A, J \subset B \)

Best local alignment score:

\[ M(A, B) = \max \{ S(I, J) : I \subset A, J \subset B \} \]

where \( S(I, J) \) is the score for substrings I and J.
Allowing preceding and trailing indels

- First row and column initialised to zero:
  \( M_{i,0} = M_{0,j} = 0 \)
Recursion for local alignment

- $M_{i,j} = \max \{ \$
- $M_{i-1,j-1} + s(a_i, b_i)$, 
- $M_{i-1,j} - \delta$, 
- $M_{i,j-1} - \delta$, 
- $0 \}$
Finding best local alignment

- Optimal score is the highest value in the matrix

\[ M(A, B) = \max \{ S(I, J) : I \subset A, J \subset B \} \]

\[ = \max_{i,j} M_{i,j} \]

- Best local alignment can be found by backtracking from the highest value in M
## Local alignment: example

</table>
Non-uniform mismatch penalties

- We used uniform penalty for mismatches:
  \[ s('A', 'C') = s('A', 'G') = \ldots = s('G', 'T') = \mu \]

- Transition mutations (A->G, G->A, C->T, T->C) are approximately twice as frequent than transversions (A->T, T->A, A->C, G->T)
  - use non-uniform mismatch penalties collected into a substitution matrix

Gaps in alignment

- Gap is a succession of indels in alignment

\[
\begin{matrix}
C & T & - & - & - & A & A \\
C & T & C & G & C & A & A \\
\end{matrix}
\]

- Previous model scored a length k gap as \( w(k) = -k\delta \)
- Replication processes may produce longer stretches of insertions or deletions
  - In coding regions, insertions or deletions of codons may preserve functionality
Gap open and extension penalties (2)

- We can design a score that allows the penalty opening gap to be larger than extending the gap:
  \[ w(k) = -\alpha - \beta(k - 1) \]
- Gap open cost \( \alpha \), Gap extension cost \( \beta \)
- Our previous algorithm can be extended to use \( w(k) \)
  (not discussed on this course)
Amino acid sequences

- We have discussed mainly DNA sequences
- Amino acid sequences can be aligned as well
- However, the design of the substitution matrix is more involved because of the larger alphabet
- More on the topic in the course Biological sequence analysis
Demonstration of the EBI web site

- European Bioinformatics Institute (EBI) offers many biological databases and bioinformatics tools at http://www.ebi.ac.uk/
Sequence Alignment (chapter 6)

- The biological problem
- Global alignment
- Local alignment
- *Multiple alignment*
Multiple alignment

- Consider a set of $n$ sequences on the right
  - Orthologous sequences from different organisms
  - Paralogs from multiple duplications
- How can we study relationships between these sequences?

```
Optimal alignment of three sequences

- Alignment of $A = a_1a_2...a_i$ and $B = b_1b_2...b_j$ can end either in $(-, b_j)$, $(a_i, b_j)$ or $(a_i, -)$

- $2^2 - 1 = 3$ alternatives

- Alignment of $A$, $B$ and $C = c_1c_2...c_k$ can end in $2^3 - 1$ ways: $(a_i, -, -)$, $(-, b_j, -)$, $(-, -, c_k)$, $(-, b_j, c_k)$, $(a_i, -, c_k)$, $(a_i, b_j, -)$ or $(a_i, b_j, c_k)$

- Solve the recursion using three-dimensional dynamic programming matrix: $O(n^3)$ time and space

- Generalizes to $n$ sequences but impractical with moderate number of sequences
Multiple alignment in practice

- In practice, real-world multiple alignment problems are usually solved with heuristics

- Progressive multiple alignment
  - Choose two sequences and align them
  - Choose third sequence w.r.t. two previous sequences and align the third against them
  - Repeat until all sequences have been aligned
  - Different options how to choose sequences and score alignments
Multiple alignment in practice

- Profile-based progressive multiple alignment: CLUSTALW
  - Construct a distance matrix of all pairs of sequences using dynamic programming
  - Progressively align pairs in order of decreasing similarity
  - CLUSTALW uses various heuristics to contribute to accuracy
Additional material

- R. Durbin, S. Eddy, A. Krogh, G. Mitchison: Biological sequence analysis
- N. C. Jones, P. A. Pevzner: An introduction to bioinformatics algorithms
- Course Biological sequence analysis in Spring 2008
Chapter 7: Rapid alignment methods: FASTA and BLAST

- The biological problem
- Search strategies
- FASTA
- BLAST
The biological problem

- Global and local alignment algorithms are slow in practice
- Consider the scenario of aligning a *query sequence* against a large database of sequences
  - New sequence with unknown function
- For instance, the size of NCBI GenBank in January 2007 was 65,369,091,950 bases (61,132,599 sequences)
Problem with large amount of sequences

- Exponential growth in both number and total length of sequences
- Possible solution: Compare against model organisms only
- With large amount of sequences, changes are that matches occur by random
  - Need for statistical analysis
Application of sequence alignment: shotgun sequencing

Shotgun sequencing is a method for sequencing whole-organism genomes

- First, a large number of short sequences (~500-1000 bp), or *reads* are generated from the genome
- Reads are contiguous subsequences (substrings) of the genome
- Due to sequencing errors and repetitions in the reads, the genome has been covered multiple times by reads
Shotgun sequencing

- Ordering of the reads is initially unknown
- Overlaps resolved by aligning the reads
- In a $3 \times 10^9$ bp genome with 500 bp reads and 5x coverage, there are $\sim 10^7$ reads and $\sim 10^7(10^7-1)/2 = \sim 5 \times 10^{13}$ pairwise sequence comparisons
Shotgun sequencing

- \(~5\times10^{13}\) pairwise sequence comparisons
- Recall that local alignment takes \(O(nm)\) time, where \(n\) and \(m\) are sequence lengths
- Already with \(n=m=500\), the computation cost is prohibitive
Search strategies

- How to speed up the computation?
  - Find ways to limit the number of pairwise comparisons
- Compare the sequences at word level to find out common words
  - Word means here a k-tuple (or a k-word), a substring of length k
Analyzing the word content

- Example query string $I$: TGATGATGAAGACATCAG
- For $k = 8$, the set of $k$-tuples of $I$ is
  
  TGATGATG
  GATGATGA
  ATGATGAA
  TGATGAAG
  ...
  GACATCAG
Analyzing the word content

- There are $n-k+1$ $k$-tuples in a string of length $n$
- If at least one word of $I$ is not found from another string $J$, we know that $I$ differs from $J$
- Need to consider statistical significance: $I$ and $J$ might share words by chance only
- Let $n=|I|$ and $m=|J|$
Word lists and comparison by content

- The k-words of $I$ can be arranged into a table of word occurrences $L_w(I)$
- Consider the k-words when $k=2$ and $I=$GCATCGGC:
  
  \[
  \text{GC, CA, AT, TC, CG, GG, GC}
  \]

  \[
  \begin{array}{ll}
  \text{AT: 3} \\
  \text{CA: 2} \\
  \text{CG: 5} \\
  \text{GC: 1, 7} & \text{Start indecies of k-word GC in I} \\
  \text{GG: 6} \\
  \text{TC: 4} & \text{Building } L_w(I) \text{ takes } O(n) \text{ time}
  \end{array}
  \]
Common k-words

- Number of common k-words in I and J can be computed using $L_w(I)$ and $L_w(J)$
- For each word $w$ in I, there are $|L_w(J)|$ occurrences in J
- Therefore I and J have $\sum_w |L_w(I)||L_w(J)|$ common words
- This can be computed in $O(n + m + 4^k)$ time
  - $O(n + m)$ time to build the lists
  - $O(4^k)$ time to calculate the sum
Common k-words

I = GCATCGGC
J = CCATCGGCAATC

10 in total
Properties of the common word list

- Exact matches can be found using binary search (e.g., where TCGT occurs in I?)
  - $O(\log 4^k)$ time
- For large $k$, the table size is too large to compute the common word count in the previous fashion
- Instead, an approach based on merge sort can be utilised (details skipped, see course book)
- The common k-word technique can be combined with the local alignment algorithm to yield a rapid alignment approach
Chapter 7: Rapid alignment methods: FASTA and BLAST

- The biological problem
- Search strategies
  - FASTA
  - BLAST
FASTA

- FASTA is a multistep algorithm for sequence alignment (Wilbur and Lipman, 1983)
- The sequence file format used by the FASTA software is widely used by other sequence analysis software
- Main idea:
  - Choose regions of the two sequences that look promising (have some degree of similarity)
  - Compute local alignment using dynamic programming in these regions
FASTA outline

- FASTA algorithm has five steps:
  - 1. Identify common k-words between I and J
  - 2. Score diagonals with k-word matches, identify 10 best diagonals
  - 3. Rescore initial regions with a substitution score matrix
  - 4. Join initial regions using gaps, penalise for gaps
  - 5. Perform dynamic programming to find final alignments
Dot matrix comparisons

- Word matches in two sequences I and J can be represented as a dot matrix.
- Dot matrix element \((i, j)\) has "a dot", if the word starting at position \(i\) in I is identical to the word starting at position \(j\) in J.
- The dot matrix can be plotted for various \(k\).

\[
\begin{align*}
I &= \ldots \text{ATCGGATCA} \ldots \\
J &= \ldots \text{TGGTGTCGC} \ldots 
\end{align*}
\]
Dot matrix (k=1,4,8,16)
for two DNA sequences
X85973.1 (1875 bp)
Y11931.1 (2013 bp)
Dot matrix
(k=1,4,8,16) for two protein sequences
CAB51201.1 (531 aa)
CAA72681.1 (588 aa)

Shading indicates now the match score according to a score matrix
(Blosum62 here)
We would like to find high scoring diagonals of the dot matrix.

Let's index diagonals by the offset, $l = i - j$.
Computing diagonal sums

- As an example, let's compute diagonal sums for \( I = \text{GCATCGGC}, J = \text{CCATCGCCATCG}, k = 2 \)
- 1. Construct k-word list \( L_w(J) \)
- 2. Diagonal sums \( S_1 \) are computed into a table, indexed with the offset and initialised to zero

|   | -10 | -9 | -8 | -7 | -6 | -5 | -4 | -3 | -2 | -1 | 0 | 1 | 2 | 3 | 4 | 5 | 6 |
|---|-----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|
|   | 0   | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0  | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

Introduction to bioinformatics, Autumn 2007
Computing diagonal sums

3. Go through k-words of I, look for matches in $L_w(J)$ and update diagonal sums

For the first 2-word in I, GC, $L_{GC}(J) = \{6\}$.

We can then update the sum of diagonal $l = i – j = 1 – 6 = -5$ to $S_{-5} := S_{-5} + 1 = 0 + 1 = 1$
Computing diagonal sums

3. Go through k-words of I, look for matches in $L_w(J)$ and update diagonal sums

Next 2-word in I is CA, for which $L_{CA}(J) = \{2, 8\}$.

Two diagonal sums are updated:

$I = i - j = 2 - 2 = 0$
$S_0 := S_0 + 1 = 0 + 1 = 1$

$I = i - j = 2 - 8 = -6$
$S_{-6} := S_{-6} + 1 = 0 + 1 = 1$
3. Go through k-words of I, look for matches in $L_w(J)$ and update diagonal sums

Next 2-word in I is AT, for which $L_{AT}(J) = \{3, 9\}$.

Two diagonal sums are updated:

$$l = i - j = 3 - 3 = 0$$
$$S_0 := S_0 + 1 = 1 + 1 = 2$$

$$l = i - j = 3 - 9 = -6$$
$$S_{-6} := S_{-6} + 1 = 1 + 1 = 2$$
Computing diagonal sums

After going through the k-words of $I$, the result is:

$$
\begin{array}{cccccccccccccccc}
1 & 10 & -9 & -8 & -7 & -6 & -5 & -4 & -3 & -2 & -1 & 0 & 1 & 2 & 3 & 4 & 5 & 6 \\
S_1 & 0 & 0 & 0 & 0 & 4 & 1 & 0 & 0 & 0 & 0 & 4 & 1 & 0 & 0 & 0 & 0 & 0 \\
\end{array}
$$
Algorithm for computing diagonal sum of scores

\[ S_l := 0 \text{ for all } 1 - m \leq l \leq n - 1 \]

Compute \( L_w(J) \) for all words \( w \)

for \( i := 1 \) to \( n - k - 1 \) do

\[ w := I_i I_{i+1} \ldots I_{i+k-1} \]

for \( j \in L_w(J) \) do

\[ l := i - j \]

\[ S_l := S_l + 1 \quad \text{Match score is here 1} \]

end

end
INTRODUCTION TO BIOINFORMATICS, AUTUMN 2007

FASTA outline

FASTA algorithm has five steps:

1. Identify common k-words between I and J
2. Score diagonals with k-word matches, identify 10 best diagonals
3. Rescore initial regions with a substitution score matrix
4. Join initial regions using gaps, penalise for gaps
5. Perform dynamic programming to find final alignments
Rescoring initial regions

- Each high-scoring diagonal chosen in the previous step is rescored according to a score matrix.
- This is done to find subregions with identities shorter than \( k \).
- Non-matching ends of the diagonal are trimmed.

\[
\begin{align*}
I: & \quad CCCATCCGCCCATCG \\
J: & \quad CCCAAGCGCAATCA
\end{align*}
\]

75% identity, no 4-word identities

\[
\begin{align*}
I': & \quad C\color{green}CATCGCCCATCG \\
J': & \quad ACA\color{green}ATCAAAA
\end{align*}
\]

33% identity, one 4-word identity
Joining diagonals

- Two offset diagonals can be joined with a gap, if the resulting alignment has a higher score
- Separate gap open and extension are used
- Find the best-scoring combination of diagonals
FASTA outline

FASTA algorithm has five steps:

1. Identify common k-words between I and J
2. Score diagonals with k-word matches, identify 10 best diagonals
3. Rescore initial regions with a substitution score matrix
4. Join initial regions using gaps, penalise for gaps
5. Perform dynamic programming to find final alignments
Local alignment in the highest-scoring region

- Last step of FASTA: perform local alignment using dynamic programming around the highest-scoring.
- Region to be aligned covers \(-w\) and \(+w\) offset diagonal to the highest-scoring diagonals.
- With long sequences, this region is typically very small compared to the whole \(n \times m\) matrix.

Dynamic programming matrix \(M\) filled only for the green region.
Properties of FASTA

- Fast compared to local alignment using dynamic programming only
  - Only a narrow region of the full matrix is aligned
- Increasing parameter k decreases the number of hits: increases specificity, decreases sensitivity
- FASTA can be very specific when identifying long regions of low similarity
  - Specific method does not produce many incorrect results
  - Sensitive method produces many of the correct results
Properties of FASTA

- FASTA looks for initial exact matches to query sequence
  - Two proteins can have very different amino acid sequences and still be biologically similar
  - This may lead into a lack of sensitivity with diverged sequences
Demonstration of FASTA at EBI

- http://www.ebi.ac.uk/ fasta/

- Note that parameter ktup in the software corresponds to parameter k in lectures
Chapter 7: Rapid alignment methods: FASTA and BLAST

- The biological problem
- Search strategies
- FASTA
- BLAST
BLAST: Basic Local Alignment Search Tool

- BLAST (Altschul et al., 1990) and its variants are some of the most common sequence search tools in use

- Roughly, the basic BLAST has three parts:
  1. Find local alignments between the query sequence and a database sequence (“seed hits”)
  2. Extend seed hits into high-scoring local alignments
  3. Calculate p-values and a rank ordering of the local alignments

- High-scoring local alignments are called high scoring segment pairs (HSPs)

- Gapped BLAST introduced in 1997 allows for gaps in alignments
Finding seed hits

First, we generate a set of *neighborhood sequences* for given $k$, *match score matrix* and threshold $T$

Neighborhood sequences of a $k$-word $w$ include all strings of length $k$ that, when aligned against $w$, have the alignment score at least $T$

For instance, let $I = \text{GCATCGGC}$, $J = \text{CCATCGCCATCG}$ and $k = 5$, match score be 1, mismatch score be 0 and $T = 4$
Finding seed hits

I = GCATCGGC, J = CCATCGCCATCG, k = 5, match score 1, mismatch score 0, T = 4

This allows for one mismatch in each k-word

The neighborhood of the first k-word of I, GCATC, is GCATC and the 15 sequences

\[
\begin{align*}
A & \quad A & \quad C & \quad A & \quad A \\
CCATC, G & \quad GATC, GC & \quad GTC, GCA & \quad CC, GCAT & \quad G \\
T & \quad T & \quad T & \quad G & \quad T
\end{align*}
\]
Finding seed hits

- \( I = \text{GCATCGGC} \) has 4 k-words and thus \( 4 \times 16 = 64 \) 5-word patterns (seed hits) to locate in \( J \)

- These patterns can be found using exact search in time proportional to the sum of pattern lengths + length of \( J \) + number of matches (Aho-Corasick algorithm)
  - Methods for pattern matching are developed on course 58093 String processing algorithms
Extending seed hits: original BLAST

- Initial seed hits are extended
- Extensions do not add gaps to the alignment
- Sequence is extended into a HSP until the alignment score drops below the maximum attained score minus a threshold parameter value
- All statistically significant HSPs reported

Extending seed hits: gapped BLAST

- In later version of BLAST, two seed hits have to be found on the same diagonal
  - Hits have to be non-overlapping
  - If the hits are closer than $A$ (additional parameter), then they are joined into a HSP

- Threshold value $T$ is lowered to achieve comparable sensitivity

- If the resulting HSP achieves a score at least $S_g$, a \textit{gapped extension} is triggered

Gapped extensions of HSPs

- Local alignment is performed starting from the HSP
- Dynamic programming matrix filled in "forward" and "backward" directions (see figure)
- Skip cells where value would be $X_g$ below the best alignment score found so far
Estimating the significance of results

- In general, we have a score \( S(D, X) = s \) for a sequence \( X \) found in database \( D \)
- BLAST rank-orders the sequences found by p-values
- The p-value for this hit is \( P(S(D, Y) \geq s) \) where \( Y \) is a random sequence
  - Measures the amount of ”surprise” of finding sequence \( X \)
- A smaller p-value indicates more significant hit
  - A p-value of 0.1 means that one-tenth of random sequences would have as large score as our result
Estimating the significance of results

- In BLAST, p-values are computed roughly as follows
- There are nm places to begin an optimal alignment in the n x m alignment matrix
- Optimal alignment is preceded by a mismatch and has t matching (identical) letters
  - (Assume match score 1 and mismatch score 0)
- Let \( p = P(\text{two random letters are equal}) \)
- The probability of having a mismatch and then t matches is \( (1-p)p^t \)
Estimating the significance of results

- We model this event by a Poisson distribution (why?) with mean $\lambda = nm(1-p)p^t$
- $P(\text{there is local alignment } t \text{ or longer})$
  - $= 1 - P(\text{no such event})$
  - $= 1 - e^{-\lambda} = 1 - \exp(-nm(1-p)p^t)$
- An equation of the same form is used in Blast:
  - $E\text{-value} = P(S(D, Y) \geq s) \approx 1 - \exp(-nm\gamma\xi^t)$ where $\gamma > 0$ and $0 < \xi < 1$
- Parameters $\gamma$ and $\xi$ are estimated from data
Scoring amino acid alignments

- We need a way to compute the score $S(D, X)$ for aligning the sequence $X$ against database $D$.
- Scoring DNA alignments was discussed previously.
- Constructing a scoring model for amino acids is more challenging:
  - 20 different amino acids vs. 4 bases.
- Figure shows the molecular structures of the 20 amino acids.

Scoring amino acid alignments

- Substitutions between chemically similar amino acids are more frequent than between dissimilar amino acids.
- We can check our scoring model against this:

Score matrices

- Scores \( s = S(D, X) \) are obtained from score matrices
- Let \( A = A_1a_2\ldots a_n \) and \( B = b_1b_2\ldots b_n \) be sequences of equal length (no gaps allowed to simplify things)
- To obtain a score for alignment of \( A \) and \( B \), where \( a_i \) is aligned against \( b_i \), we take the ratio of two probabilities
  - The probability of having \( A \) and \( B \) where the characters match (match model \( M \))
  - The probability that \( A \) and \( B \) were chosen randomly (random model \( R \))
Score matrices: random model

- Under the random model, the probability of having $X$ and $Y$ is

$$P(A, B | R) = \prod_{i} q_{ai} \prod_{i} q_{bi}$$

where $q_{xi}$ is the probability of occurrence of amino acid type $x_i$

- Position where an amino acid occurs does not affect its type
Score matrices: match model

- Let $p_{ab}$ be the probability of having amino acids of type $a$ and $b$ aligned against each other given they have evolved from the same ancestor $c$

- The probability is

$$P(A, B | M) = \prod_i p_{a_i b_i}$$
Score matrices: log-odds ratio score

We obtain the score $S$ by taking the ratio of these two probabilities

$$\frac{P(A, B | M)}{P(A, B | R)} = \frac{\prod_i p_{a_i} b_i}{\prod_i q_{a_i} \prod_i q_{b_i}} = \prod_i \frac{p_{a_i} b_i}{q_{a_i} q_{b_i}}$$

and taking a logarithm of the ratio

$$S = \log_2 \frac{P(A, B | M)}{P(A, B | R)} = \sum_{i=1}^n \log_2 \frac{p_{a_i} b_i}{q_{a_i} q_{b_i}} = \sum_{i=1}^n s(a_i, b_i)$$
Score matrices: log-odds ratio score

\[ S = \log_2 \frac{P(A, B|M)}{P(A, B|R)} = \sum_{i=1}^{n} \log_2 \frac{p_{a_i b_i}}{q_{a_i} q_{b_i}} = \sum_{i=1}^{n} s(a_i, b_i) \]

- The score \( S \) is obtained by summing over character pair-specific scores:

\[ s(a, b) = \log_2 \frac{p_{ab}}{q_a q_b} \]

- The probabilities \( q_a \) and \( p_{ab} \) are extracted from data
Calculating score matrices for amino acids

- Probabilities $q_a$ are in principle easy to obtain:
  - Count relative frequencies of every amino acid in a sequence database

$$s(a, b) = \log_2 \frac{p_{ab}}{q_a q_b}$$
Calculating score matrices for amino acids

- To calculate $p_{ab}$ we can use a known pool of aligned sequences
- BLOCKS is a database of highly conserved regions for proteins
- It lists multiply aligned, ungapped and conserved protein segments
- Example from BLOCKS shows genes related to human gene associated with DNA-repair defect xeroderma pigmentosum

$$s(a, b) = \log_2 \frac{p_{ab}}{q_a q_b}$$

BLOSUM matrix

- BLOSUM is a score matrix for amino acid sequences derived from BLOCKS data.
- First, count pairwise matches $f_{x,y}$ for every amino acid type pair $(x, y)$.
- For example, for column 3 and amino acids L and W, we find 8 pairwise matches: $f_{L,W} = f_{W,L} = 8$.

RPLWVAPD
RPLWVAPR
RPLWVAPN
PLWISPSD
RPLWACAD
PLWINPID
RPIWVCPD
Creating a BLOSUM matrix

- Probability $p_{ab}$ is obtained by dividing $f_{ab}$ with the total number of pairs (note difference with course book):

$$p_{ab} = \frac{f_{ab}}{\sum_{x=1}^{20} \sum_{y=1}^{x} f_{xy}}$$

- We get probabilities $q_a$ by

$$q_a = \sum_{b=1}^{20} p_{ab}$$
Creating a BLOSUM matrix

- The probabilities $p_{ab}$ and $q_a$ can now be plugged into

$$s(a, b) = \log_2 \frac{p_{ab}}{q_a q_b}$$

to get a 20 x 20 matrix of scores $s(a, b)$.

- Next slide presents the BLOSUM62 matrix
  - Values scaled by factor of 2 and rounded to integers
  - Additional step required to take into account expected evolutionary distance
  - Described in the course book in more detail

MQLEANADTSV

\[ s = \sum_{i=1}^{11} s(a_i, b_i) \]

\[ = 2 + 5 - 3 - 4 + 4 + 0 + 4 + 0 - 2 + 0 + 1 \]

\[ = 7 \]
Demonstration of BLAST at NCBI

Inferring the Past: Phylogenetic Trees (chapter 12)

- The biological problem
- Parsimony and distance methods
- Models for mutations and estimation of distances
- Maximum likelihood methods
Phylogeny

- We want to study ancestor-descendant relationships, or *phylogeny*, among groups of organisms
- Groups are called *taxa* (singular: *taxon*)
- Organisms are usually called *operational taxonomic units* or *OTUs* in the context of phylogeny
Phylogenetic trees

- Leaves (external nodes) ~ species, observed (OTUs)
- Internal nodes ~ ancestral species/divergence events, not observed
- Unrooted tree does not specify ancestor-descendant relationships beyond the observation “leaves are not ancestors”

Unrooted tree with 5 leaves and 3 internal nodes.

Is node 7 ancestor of node 6?
Phylogenetic trees

• Rooting a tree specifies all ancestor-descendant relationships in the tree

• Root is the ancestor to the other species

• There are n-1 ways to root a tree with n nodes
Questions

- Can we enumerate all possible phylogenetic trees for \( n \) species (or sequences?)
- How to score a phylogenetic tree with respect to data?
- How to find the best phylogenetic tree given data?
Finding the best phylogenetic tree: naive method

- How can we find the phylogenetic tree that best represents the data?
- Naive method: enumerate all possible trees
- How many different trees are there of $n$ species?
- Denote this number by $b_n$
Enumerating unordered trees

- Start with the only unordered tree with 3 leaves \( b_3 = 1 \)

```
  1
 /   \
3     2
```

- Consider all ways to add a leaf node to this tree

```
  1
 /   \
1     2
 /   /
4   3  4
```

- Fourth node can be added to 3 different branches (edges), creating 1 new internal branch

```
  1
 /   \
1     2
 /   /
2   4  4
```

- Total number of branches is \( n \) external and \( n - 3 \) internal branches

- Unrooted tree with \( n \) leaves has \( 2n - 3 \) branches
Enumerating unordered trees

- Thus, we get the number of unrooted trees
  \[ b_n = (2(n - 1) - 3)b_{n-1} = (2n - 5)b_{n-1} \]
  \[ = (2n - 5) \times (2n - 7) \times \ldots \times 3 \times 1 \]
  \[ = (2n - 5)! / ((n-3)!2^{n-3}), \quad n > 2 \]

- Number of rooted trees \( b'_n \) is
  \[ b'_n = (2n - 3)b_n = (2n - 3)! / ((n-2)!2^{n-2}), \quad n > 2 \]
  that is, the number of unrooted trees times the number of branches in the trees
Number of possible rooted and unrooted trees

</table>
Too many trees?

- We can’t construct and evaluate every phylogenetic tree even for a smallish number of species

- Better alternative is to
  - Devise a way to evaluate an individual tree against the data
  - Guide the search using the evaluation criteria to reduce the search space
Inferring the Past: Phylogenetic Trees (chapter 12)

- The biological problem
- *Parsimony and distance methods*
- Models for mutations and estimation of distances
- Maximum likelihood methods
Parsimony method

- The parsimony method finds the tree that explains the observed sequences with a minimal number of substitutions

- Method has two steps
  - Compute smallest number of substitutions for a given tree with a parsimony algorithm
  - Search for the tree with the minimal number of substitutions
Parsimony: an example

Consider the following short sequences

1 ACTTT
2 ACATT
3 AACGT
4 AATGT
5 AATTT

There are 105 possible rooted trees for 5 sequences

Example: which of the following trees explains the sequences with least number of substitutions?
This tree explains the sequences with 4 substitutions
4 substitutions...

First tree is more parsimonious!

6 substitutions...
Computing parsimony

- Parsimony treats each site (position in a sequence) independently
- Total parsimony cost is the sum of parsimony costs of each site
- We can compute the minimal parsimony cost for a given tree by
  - First finding out possible assignments at each node, starting from leaves and proceeding towards the root
  - Then, starting from the root, assign a letter at each node, proceeding towards leaves
Labelling tree nodes

1. An unrooted tree with $n$ leaves contains $2n-1$ nodes altogether.
2. Assign the following labels to nodes in a rooted tree:
   - leaf nodes: 1, 2, …, $n$
   - internal nodes: $n+1$, $n+2$, …, $2n-1$
   - root node: $2n-1$
3. The label of a child node is always smaller than the label of the parent node.
Parsimony algorithm: first phase

Find out possible assignments at every node for each site $u$ independently. Denote site $u$ in sequence $i$ by $s_{i,u}$.

For $i := 1, \ldots, n$ do

$$F_i := \{s_{i,u}\} \quad \% \text{possible assignments at node } i$$

$$L_i := 0 \quad \% \text{number of substitutions up to node } i$$

For $i := n+1, \ldots, 2n-1$ do

Let $j$ and $k$ be the children of node $i$

If $F_j \cap F_k = \emptyset$ then

$$L_i := L_j + L_k + 1, \quad F_i := F_j \cup F_k$$

else $L_i := L_j + L_k, \quad F_i := F_j \cap F_k$
Parsimony algorithm: first phase

Choose $u = 3$ (for example, in general we do this for all $u$)

$F_1 := \{T\}$
$L_1 := 0$

$F_2 := \{A\}$
$L_2 := 0$

$F_3 := \{C\}$, $L_3 := 0$

$F_4 := \{T\}$, $L_4 := 0$

$F_5 := \{T\}$, $L_5 := 0$
Parsimony algorithm: first phase

\[ F_6 := F_3 \cup F_4 = \{C, T\} \]
\[ L_6 := L_3 + L_4 + 1 = 1 \]

\[ F_7 := F_5 \cap F_6 = \{T\} \]
\[ L_7 := L_5 + L_6 = 1 \]

\[ F_8 := F_1 \cup F_2 = \{A, T\} \]
\[ L_8 := L_1 + L_2 + 1 = 1 \]

\[ F_9 := F_7 \cap F_8 = \{T\} \]
\[ L_9 := L_7 + L_8 = 2 \]

\( \Rightarrow \) Parsimony cost for site 3 is 2
Parsimony algorithm: second phase

- Backtrack from the root and assign $x \in F_i$ at each node
- If we assigned $y$ at parent of node $i$ and $y \in F_i$, then assign $y$
- Else assign $x \in F_i$ by random
Parsimony algorithm: second phase

At node 6, the algorithm assigns T because T was assigned to parent node 7 and T ∈ F_6.

T is assigned to node 8 for the same reason.

The other nodes have only one possible letter to assign.
Parsimony algorithm

First and second phase are repeated for each site in the sequences, summing the parsimony costs at each site.

```
AACGT  AATGT  AATTT  ACATT  ACTTT
  3     4      5      2      1
     6T     7T   9T
        8T
```
Properties of parsimony algorithm

- Parsimony algorithm requires that the sequences are of same length
  - First align the sequences against each other and remove indels
  - Then compute parsimony for the resulting sequences
- Is the most parsimonious tree the correct tree?
  - Not necessarily but it explains the sequences with least number of substitutions
  - We can assume that the probability of having fewer mutations is higher than having many mutations
Finding the most parsimonious tree

- Parsimony algorithm calculates the parsimony cost for a given tree...
- ...but we still have the problem of finding the tree with the lowest cost
- Exhaustive search (enumerating all trees) is in general impossible
- More efficient methods exist, for example
  - Probabilistic search
  - Branch and bound
Branch and bound in parsimony

We can exploit the fact that adding edges to a tree can only increase the parsimony cost.

```
  {T}
  /   \
1   2  
AATGT  AATT T

{C,T}
  /   \
3    \2
AACGT  {T}  AATT T

cost 0               cost 1
```
Branch and bound in parsimony

Branch and bound is a general search strategy where
- Each solution is potentially generated
- Track is kept of the best solution found
- If a partial solution cannot achieve better score, we abandon the current search path

In parsimony…
- Start from a tree with 1 sequence
- Add a sequence to the tree and calculate parsimony cost
- If the tree is complete, check if found the best tree so far
- If tree is not complete and cost exceeds best tree cost, do not continue adding edges to this tree
Branch and bound graphically

Partial tree, no best complete tree constructed yet

Complete tree: calculate parsimony cost and store

Partial tree, cost exceeds the cost of the best tree this far
Distance methods

- The parsimony method works on sequence (character string) data
- We can also build phylogenetic trees in a more general setting
- *Distance methods* work on a set of pairwise distances $d_{ij}$ for the data
- Distances can be obtained from phenotypes as well as from genotypes (sequences)
Distances in a phylogenetic tree

- Distance matrix $D = (d_{ij})$ gives pairwise distances for leaves of the phylogenetic tree.
- In addition, the phylogenetic tree will now specify distances between leaves and internal nodes.
  - Denote these with $d_{ij}$ as well.

Distance $d_{ij}$ states how far apart species $i$ and $j$ are evolutionary (e.g., number of mismatches in aligned sequences).
Distances in evolutionary context

Distances $d_{ij}$ in evolutionary context satisfy the following conditions

- Symmetry: $d_{ij} = d_{ji}$ for each $i, j$
- Distinguishability: $d_{ij} \neq 0$ if and only if $i \neq j$
- Triangle inequality: $d_{ij} \leq d_{ik} + d_{kj}$ for each $i, j, k$

Distances satisfying these conditions are called metric.

In addition, evolutionary mechanisms may impose additional constraints on the distances

- additive and ultrametric distances
Additive trees

A tree is called *additive*, if the distance between any pair of leaves \((i, j)\) is the sum of the distances between the leaves and the first node \(k\) that they share in the tree

\[
d_{ij} = d_{ik} + d_{jk}
\]

"Follow the path from the leaf \(i\) to the leaf \(j\) to find the exact distance \(d_{ij}\) between the leaves."

<td>2</td>
<td>0</td>
</tr>
</tbody>
</table>

![Additive Tree Diagram]

In the diagram, the branches represent the additive distances between the characters A, B, C, and D.
Ultrametric trees

A rooted additive tree is called a *ultrametric tree*, if the distances between any two leaves $i$ and $j$, and their common ancestor $k$ are equal

$$d_{ik} = d_{jk}$$

Edge length $d_{ij}$ corresponds to the time elapsed since divergence of $i$ and $j$ from the common parent

In other words, edge lengths are measured by a *molecular clock* with a constant rate
Identifying ultrametric data

- We can identify distances to be ultrametric by the three-point condition:

  D corresponds to an ultrametric tree if and only if for any three species i, j and k, the distances satisfy

  \[ d_{ij} \leq \max(d_{ik}, d_{kj}) \]

- If we find out that the data is ultrametric, we can utilise a simple algorithm to find the corresponding tree
Ultrametric trees
Only vertical segments of the tree have correspondence to some distance $d_{ij}$:

Horizontal segments act as connectors.

Observation time
Ultrametric trees

$d_{ik} = d_{jk}$ for any two leaves $i, j$ and any ancestor $k$ of $i$ and $j$
Ultrametric trees

Three-point condition: there exists no leaf $i$, $j$ for which $d_{ij} > \max(d_{ik}, d_{jk})$ for some leaf $k$. 

Observation time
UPGMA algorithm

- UPGMA (unweighted pair group method using arithmetic averages) constructs a phylogenetic tree via clustering
- The algorithm works by at the same time
  - Merging two clusters
  - Creating a new node on the tree
- The tree is built from leaves towards the root
- UPGMA produces a ultrametric tree
Cluster distances

Let distance $d_{ij}$ between clusters $C_i$ and $C_j$ be

$$d_{ij} = \frac{1}{|C_i||C_j|} \sum_{p \in C_i, q \in C_j} d_{pq}$$

that is, the average distance between points (species) in the cluster.
UPGMA algorithm

- **Initialisation**
  - Assign each point i to its own cluster $C_i$
  - Define one leaf for each sequence, and place it at height zero

- **Iteration**
  - Find clusters i and j for which $d_{ij}$ is minimal
  - Define new cluster k by $C_k = C_i \cup C_j$, and define $d_{kl}$ for all l
  - Define a node k with children i and j. Place k at height $d_{ij}/2$
  - Remove clusters i and j

- **Termination:**
  - When only two clusters i and j remain, place root at height $d_{ij}/2$
In naive implementation, each iteration takes $O(n^2)$ time with $n$ sequences => algorithm takes $O(n^3)$ time

The algorithm can be implemented to take only $O(n^2)$ time (Gronau & Moran, 2006)
Problem solved?

- We now have a simple algorithm which finds a ultrametric tree
  - If the data is ultrametric, then there is exactly one ultrametric tree corresponding to the data (we skip the proof)
  - The tree found is then the ”correct” solution to the phylogeny problem, if the assumptions hold
- Unfortunately, the data is not ultrametric in practice
  - Measurement errors distort distances
  - *Basic assumption of a molecular clock does not hold usually very well*
Incorrect reconstruction of non-ultrametric data by UPGMA

Tree which corresponds to non-ultrametric distances

Incorrect ultrametric reconstruction by UPGMA algorithm
Checking for additivity

- How can we check if our data is additive?
- Let i, j, k and l be four \textit{distinct} species
- Compute 3 sums: $d_{ij} + d_{kl}$, $d_{ik} + d_{jl}$, $d_{il} + d_{jk}$
Four-point condition

The sums are represented by the three figures

- Left and middle sum cover all edges, right sum does not

*Four-point condition:* i, j, k and l satisfy the four-point condition if two of the sums $d_{ij} + d_{kl}$, $d_{ik} + d_{jl}$, $d_{il} + d_{jk}$ are the same, and the third one is smaller than these two
Checking for additivity

An $n \times n$ matrix $D$ is additive if and only if the four point condition holds for every 4 distinct elements $1 \leq i, j, k, l \leq n$
Finding an additive phylogenetic tree

- Additive trees can be found with, for example, the neighbor joining method (Saitou & Nei, 1987)

- The neighbor joining method produces unrooted trees, which have to be rooted by other means
  - A common way to root the tree is to use an outgroup
  - Outgroup is a species that is known to be more distantly related to every other species than they are to each other
  - Root node candidate: position where the outgroup would join the phylogenetic tree

- However, in real-world data, even additivity usually does not hold very well
Neighbor joining algorithm

- Neighbor joining works in a similar fashion to UPGMA
  - Find clusters $C_1$ and $C_2$ that minimise a function $f(C_1, C_2)$
  - Join the two clusters $C_1$ and $C_2$ into a new cluster $C$
  - Add a node to the tree corresponding to $C$
  - Assign distances to the new branches

- Differences in
  - The choice of function $f(C_1, C_2)$
  - How to assign the distances
Neighbor joining algorithm

- Recall that the distance $d_{ij}$ for clusters $C_i$ and $C_j$ was

\[
  d_{ij} = \frac{1}{|C_i||C_j|} \sum_{p \in C_i, q \in C_j} d_{pq}
\]

- Let $u(C_i)$ be the separation of cluster $C_i$ from other clusters defined by

\[
  u(C_i) = \frac{1}{n-2} \sum_{C_j} d_{ij}
\]

where $n$ is the number of clusters.
Neighbor joining algorithm

Instead of trying to choose the clusters $C_i$ and $C_j$ closest to each other, neighbor joining at the same time

- Minimises the distance between clusters $C_i$ and $C_j$ and
- Maximises the separation of both $C_i$ and $C_j$ from other clusters
Neighbor joining algorithm

- **Initialisation as in UPGMA**

- **Iteration**
  - Find clusters $i$ and $j$ for which $d_{ij} - u(C_i) - u(C_j)$ is minimal
  - Define new cluster $k$ by $C_k = C_i \cup C_j$, and define $d_{kl}$ for all $l$
  - Define a node $k$ with children $i$ and $j$. Remove clusters $i$ and $j$
  - Assign length $\frac{1}{2} d_{ij} + \frac{1}{2} (u(C_i) - u(C_j))$ to the edge $i \rightarrow k$
  - Assign length $\frac{1}{2} d_{ij} + \frac{1}{2} (u(C_j) - u(C_i))$ to the edge $j \rightarrow k$

- **Termination:**
  - When only one cluster remains

</table>

\[
\frac{1}{2} 6 + \frac{1}{2} (9 - 13) = 1
\]

\[
\frac{1}{2} 6 + \frac{1}{2} (13 - 13) = 1
\]
Inferring the Past: Phylogenetic Trees (chapter 12)

- The biological problem
- Parsimony and distance methods
- *Models for mutations and estimation of distances*
- Maximum likelihood methods
Estimation of distances

- Many alternative ways to derive the distances $d_{ij}$ exist
  - Simple solution: align each sequence pair and use the alignment score
  - This would not take into account that a change in base might revert back to the original base
  - We would then underestimate the distances
- Next: derivation of a simple stochastic model for the evolution of a DNA sequence
- Obtain the distances from the model
Estimation of distances

Key assumptions:

- mutations at sites are rare events in the course of time => poisson process
- sites evolve individually and by an identical mechanism
- number of mismatched bases is a sum of mutations at individual sites => binomial variable
A stochastic model for base substitutions

- Consider a single homologous site in two sequences
- Assume the sites diverged for time length $t$: the sites are separated by time $2t$
- Suppose that the number of substitutions in any branch of length $t$ has a Poisson distribution with mean $\lambda t$
- Probability that $k$ substitutions occur is given by the Poisson probability $e^{-\lambda t}(\lambda t)^k/(k!)$, $k = 0, 1, 2, \ldots$
Substitutions at one site

- General model: \( P(\text{substitution results in base } j \mid \text{ site was base } i) = m_{ij} \)
- Felsenstein model: \( m_{ij} = \pi_j \), with \( \pi_j \geq 0 \) and \( \pi_1 + \pi_2 + \pi_3 + \pi_4 = 1 \)
  - The previous base does not affect the outcome!
- Assume that the set of probabilities \( \pi_j \) is same at every position in the sequence
Substitutions at one site (2)

- Probability $q_{ij}(t)$ that a base $i$ at time 0 is substituted by a base $j$ a time $t$ later
  
  $q_{ij}(t) = e^{-\lambda t} + (1 - e^{-\lambda t}) \pi_j$, if $i = j$

  $q_{ij}(t) = (1 - e^{-\lambda t}) \pi_j$, otherwise
Substitutions at one site (3)

- We assume stationarity: distribution of base frequencies is the same for every time $t$
- In other words, we want that:
  \[ P(\text{base a time } t \text{ later} = j) = \pi_j^0 \]
  where $\pi_j^0$ is the frequency of base $j$ at time 0.

- For our simple model, this can be shown to hold
Estimating distances

- Distances should take into account the mutation mechanism
- Average of $\lambda t$ substitutions occur at a particular site on a branch of length $t$
- However, some of the substitutions do not change the base (A -> A or A -> G -> A, for example)
Mean number of substitutions in time $t$

- What is the chance $H$ that a substitution actually changes a base?
  \[ H = \sum \pi_i (1 - \pi_i) = 1 - \sum \pi_i^2 \]
- Average number of real substitutions is then $\lambda t H$
- Distance $K$ between two sequences is
  \[ K = 2\lambda t H \]
Estimating distances from sequence data

- We want to estimate $K = 2\lambda tH$ from sequence data.
- The chance $F_{ij}(t)$ that we observe a base $i$ in one sequence and a base $j$ in another is

$$F_{ij}(t) = \sum_{l} \pi_l q_{li}(t)q_{lj}(t)$$

by averaging over the possible ancestral nucleotides.
Estimating distances from sequence data

- Expression \( F_{ij}(t) = \sum \pi_i q_{ii}(t) q_{ij}(t) \) can be simplified by assuming that the mutation process is reversible:
  \[ \pi_i m_{ij} = \pi_j m_{ji} \text{ for all } i \neq j \]
- From this it can be shown that
  \[ \pi_i q_{ij}(t) = \pi_j q_{ji}(t) \text{ for all } i, j \text{ and } t > 0 \]
- Now the model simplifies into \( F_{ij}(t) = \pi_i q_{ij}(2t) \)
Estimating distances from sequence data

What is the probability $F = F(t)$ that the bases at a particular position in two immediate descendants of the same ancestor are identical?

$$F = \sum_i \pi_i q_{ii}(2t) = e^{-2\lambda t} + (1 - e^{-2\lambda t})(1 - H)$$
Putting the sites together

- Assume that
  - sites evolve independently of one other and
  - mutation process is identical at each site
  - The two sequences have been aligned against each other and gaps have been removed

- Do the bases at site i in the sequences differ?
  \[ X_i = 1 \text{ if the ith pair of sites differs} \]
  \[ X_i = 0 \text{ otherwise} \]
Putting the sites together (2)

1. \( P(X_i = 1) = 1 - F = (1 - e^{-2\lambda t})H \)
2. Now \( D = X_1 + \ldots + X_s \) is the number of mismatched pairs of bases
3. \( D \) is a binomial random variable with parameters \( s \) and \( 1 - F \)
4. Notice that \( D \) is the Hamming distance for the sequences
Putting the sites together (3)

- F is unknown and has to be estimated from the sequence data
- Recall that the observed proportion of successes is a good estimator of the binomial success probability: estimate $1 - F$ with $D/s$
  - $D/s = (1 - e^{-2\lambda t})H$
  - $2\lambda t = -\log(1 - D/(sH))$
  - Finally, we obtain $K = 2\lambda t H = -H \log(1 - D/(sH))$
Jukes-Cantor formula

- Estimate $2\lambda tH = -H \log(1 - D/(sH))$ of the distance $K$ is known as the Jukes-Cantor formula.
- When $H$ (chance that a substitution actually occurs) approaches 1, the estimate decreases and approaches the Poisson mean $2\lambda t$.
- $H$ is usually not known and has to be estimated from the data as well.
Inferring the Past: Phylogenetic Trees (chapter 12)

- The biological problem
- Parsimony and distance methods
- Models for mutations and estimation of distances
  - Maximum likelihood methods
Maximum likelihood methods

- Consider the tree on the right with three sequences.
- Probability $p(i_1, i_2, i_3)$ of observing bases $i_1$, $i_2$ and $i_3$ can be computed by summing over all possible ancestral bases,

$$p(i_1, i_2, i_3) = \sum_a \sum_b \pi_a q_{ai3}(t_2)q_{ab}(t_2-t_1)q_{bi2}(t_1)q_{bi1}(t_1)$$

- Hard to compute for complex trees.
Maximum likelihood estimation

- We would like to calculate likelihood \( p(i_1, i_2, \ldots, i_n) \) in the general case
- Calculations can be arranged using the peeling algorithm (see exercises)
- Basic idea is to move all summation signs as far to the right as possible
Maximum likelihood estimation

- Likelihood for the data is then obtained by multiplying the likelihoods of individual sites

- General recipe for maximum likelihood estimation:
  - Maximize over all model parameters for a *given* tree
  - Maximize previous expression over *all* possible trees
Problems with tree-building

Assumptions

- Sites evolve independently of one other
- Sites evolve according to the same stochastic model
- The tree is rooted
- The sequences are aligned
- Vertical inheritance
