Rapid alignment methods: FASTA and BLAST

- The biological problem
- Search strategies
- FASTA
- *BLAST*

257

BLAST: Basic Local Alignment Search Tool

- BLAST (Altschul et al., 1990) and its variants are some of the most common sequence search tools in use
- Roughly, the basic BLAST has three parts:
  - 1. Find *segment pairs* between the query sequence and a database sequence above score threshold ("seed hits")
  - 2. Extend seed hits into *locally maximal segment pairs*
  - 3. Calculate p-values and a rank ordering of the local alignments
- Gapped BLAST introduced in 1997 allows for gaps in alignments

258

Finding seed hits

- First, we generate a set of *neighborhood sequences* for given k, *match score matrix and threshold* T
- Neighborhood sequences of a k-word w include all strings of length k that, when aligned against w, have the alignment score at least T
- For instance, let I = GCATCGGC, J = CCATCGCCATCG and k = 5, match score be 1, mismatch score be 0 and T = 4

259

Finding seed hits

- I = GCATCGGC, J = CCATCGCCATCG, k = 5, match score 1, mismatch score 0, T = 4
- This allows for one mismatch in each k-word
- The neighborhood of the first k-word of I, GCATC, is GCATC and the 15 sequences

{A,C,T}CCATC, G{A,T}GATC, GC{C,T}GTC, GCA{A,G}CC, GCAT{A,G,T}

260

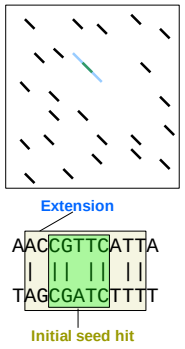
Finding seed hits

- I = GCATCGGC has 4 k-words and thus 4x16 = 64 5-word patterns to locate in J
  - Occurences of patterns in J are called seed hits
- Patterns can be found using exact search in time proportional to the sum of pattern lengths + length of J + number of matches (Aho-Corasick algorithm)
  - Methods for pattern matching are developed on course 58093 String processing algorithms
- Compare this approach to FASTA

261

Extending seed hits: original BLAST

- Initial seed hits are extended into locally maximal segment pairs or High-scoring Segment Pairs (HSP)
- Extensions do not add gaps to the alignment
- Sequence is extended until the alignment score drops below the maximum attained score minus a threshold parameter value
- All statistically significant HSPs reported

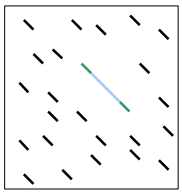


Altschul, S.F., Gish, W., Miller, W., Myers, E. W. and Lipman, D. J., *J. Mol. Biol.*, 215, 403-410, 1990

262

Extending seed hits: gapped BLAST

- In a later version of BLAST, two seed hits have to be found on the same diagonal
  - Hits have to be non-overlapping
  - If the hits are closer than A (additional parameter), then they are joined into a HSP
- Threshold value T is lowered to achieve comparable sensitivity
- If the resulting HSP achieves a score at least S_g, a *gapped extension* is triggered

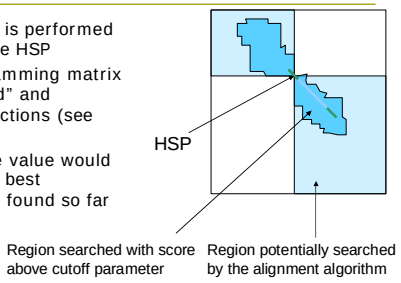


Altschul SF, Madden TL, Schäffer AA, Zhang J, Zhang Z, Miller W, and Lipman DJ, *Nucleic Acids Res.* 1;25(17), 3389-402, 1997

263

Gapped extensions of HSPs

- Local alignment is performed starting from the HSP
- Dynamic programming matrix filled in "forward" and "backward" directions (see figure)
- Skip cells where value would be X_g below the best alignment score found so far



264

Estimating the significance of results

- In general, we have a score S(D, X) = s for a sequence X found in database D
- BLAST rank-orders the sequences found by p-values
- The p-value for this hit is P(S(D, Y) ≥ s) where Y is a random sequence
  - Measures the amount of "surprise" of finding sequence X
- A smaller p-value indicates more significant hit
  - A p-value of 0.1 means that one-tenth of random sequences would have as large score as our result

265

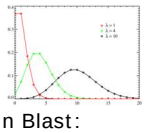
Estimating the significance of results

- In BLAST, p-values are computed roughly as follows
- There are nm places to begin an optimal alignment in the n x m alignment matrix
- Optimal alignment is preceded by a mismatch and has t matching (identical) letters
  - (Assume match score 1 and mismatch/indel score -∞)
- Let p = P(two random letters are equal)
- The probability of having a mismatch and then t matches is $(1-p)p^t$

266

Estimating the significance of results

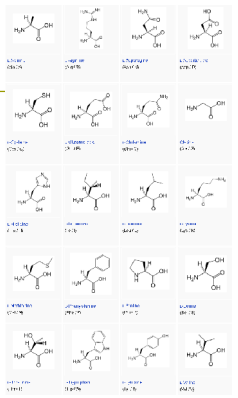
- We model this event by a Poisson distribution (why?) with mean $\lambda = nm(1-p)p^t$
- P(there is local alignment t or longer)
  $\approx 1 - P(\text{no such event})$
  $= 1 - e^{-\lambda} = 1 - \exp(-nm(1-p)p^t)$
- An equation of the same form is used in Blast:
- E-value = $P(S(D, Y) \geq s) \approx 1 - \exp(-nm\gamma\xi^t)$ where $\gamma > 0$ and $0 < \xi < 1$
- Parameters γ and ξ are estimated from data



267

Scoring amino acid alignments

- We need a way to compute the score S(D, X) for aligning the sequence X against database D
- Scoring DNA alignments was discussed previously
- Constructing a scoring model for amino acids is more challenging
  - 20 different amino acids vs. 4 bases
- Figure shows the molecular structures of the 20 amino acids

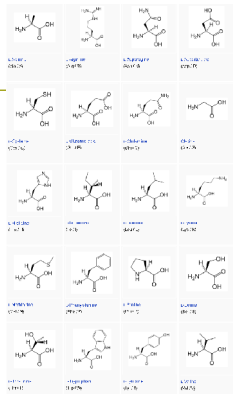


http://en.wikipedia.org/wiki/List_of_standard_amino_acids

268

Scoring amino acid alignments

- Substitutions between chemically similar amino acids are more frequent than between dissimilar amino acids
- We can check our scoring model against this



http://en.wikipedia.org/wiki/List_of_standard_amino_acids

Score matrices

- Scores s = S(D, X) are obtained from score matrices
- Let A = $A_1a_2...a_n$ and B = $b_1b_2...b_n$ be sequences of equal length (no gaps allowed to simplify things)
- To obtain a score for alignment of A and B, where a_i is aligned against b_i, we take the ratio of two probabilities
  - The probability of having A and B where the characters match (match model M)
  - The probability that A and B were chosen randomly (random model R)

Score matrices: random model

- Under the random model, the probability of having X and Y is

$$P(A,B|R) = \prod_i q_{ai} \prod_i q_{bi}$$

  where q_{xi} is the probability of occurence of amino acid type x_i
- Position where an amino acid occurs does not affect its type

Score matrices: match model

- Let p_{ab} be the probability of having amino acids of type a and b aligned against each other given they have evolved from the same ancestor c
- The probability is

$$P(A,B|M) = \prod_i p_{a_i b_i}$$

Score matrices: log-odds ratio score

- We obtain the score S by taking the ratio of these two probabilities

$$\frac{P(A,B|M)}{P(A,B|R)} = \frac{\prod_i p_{a_i b_i}}{\prod_i q_{a_i} \prod_i q_{b_i}} = \prod_i \frac{p_{a_i b_i}}{q_{a_i} q_{b_i}}$$

  and taking a logarithm of the ratio

$$S = \log_2 \frac{P(A,B|M)}{P(A,B|R)} = \sum_{i=1}^{n} \log_2 \frac{p_{a_i b_i}}{q_{a_i} q_{b_i}} = \sum_{i=1}^{n} s(a_i, b_i)$$

Score matrices: log-odds ratio score

$$S = \log_2 \frac{P(A,B|M)}{P(A,B|R)} = \sum_{i=1}^{n} \log_2 \frac{p_{a_i b_i}}{q_{a_i} q_{b_i}} = \sum_{i=1}^{n} s(a_i, b_i)$$

- The score S is obtained by summing over character pair-specific scores:

$$s(a,b) = \log_2 \frac{p_{ab}}{q_a q_b}$$

- The probabilities q_a and p_{ab} are extracted from data

Calculating score matrices for amino acids

- Probabilities q_a are in principle easy to obtain:
  - Count relative frequencies of every amino acid in a sequence database

$$s(a,b) = \log_2 \frac{p_{ab}}{q_a q_b}$$

275

Calculating score matrices for amino acids

- To calculate p_{ab} we can use a known pool of aligned sequences
- BLOCKS is a database of highly conserved regions for proteins
- It lists multiply aligned, ungapped and conserved protein segments
- Example from BLOCKS shows genes related to human gene associated with DNA-repair defect xeroderma pigmentosum

$$s(a,b) = \log_2 \frac{p_{ab}}{q_a q_b}$$

276

BLOSUM matrix

- BLOSUM is a score matrix for amino acid sequences derived from BLOCKS data
- First, count pairwise matches $f_{x,y}$ for every *amino acid type pair (x, y)*
- For example, for column 3 and amino acids L and W, we find 8 pairwise matches: $f_{L,W} = f_{W,L} = 8$

```
RPLWVAPD
RPLWVAPR
RPLWVAPN
PLWISPSD
RPLWACAD
PLWINPID
RPIWVCPD
```

277

Creating a BLOSUM matrix

- Probability p_{ab} is obtained by dividing f_{ab} with the total number of pairs (note difference with course book):

$$p_{ab} = f_{ab} / \sum_{x=1}^{20} \sum_{y=1}^{x} f_{xy}$$

- We get probabilities q_a by

$$q_a = \sum_{b=1}^{20} p_{ab}$$

```
RPLWVAPD
RPLWVAPR
RPLWVAPN
PLWISPSD
RPLWACAD
PLWINPID
RPIWVCPD
```

278

Creating a BLOSUM matrix

- The probabilities p_{ab} and q_a can now be plugged into

$$s(a,b) = \log_2 \frac{p_{ab}}{q_a q_b}$$

to get a 20 x 20 matrix of scores s(a, b).

- Next slide presents the BLOSUM62 matrix
  - Values scaled by factor of 2 and rounded to integers
  - Additional step required to take into account expected evolutionary distance
  - Described in Deonier's book in more detail
