CPU Structure and Function

Ch 12 [Sta10]
- Registers
- Instruction cycle
- Pipeline
- Dependences
- Dealing with Branches

General structure of CPU

- ALU
  - Calculations, comparisons
- Registers
  - Fast work area
- Processor bus
  - Moving bits
- Control Unit (Ohjausyksikkö)
  - What? Where? When?
  - Clock pulse
  - Generate control signals
  - What happens at the next pulse?
- MMU?
- Cache?
Registers

- Top of memory hierarchy
- User visible registers
  - Programmer / Compiler decides how to use these
  - How many? Names?
- Control and status registers
  - Some of these used indirectly by the program
    - PC, PSW, flags, …
  - Some used only by CPU internally
    - MAR, MBR, …
- Internal latches (apurekisteri) for temporal storage during instruction execution
  - Example: Instruction register (IR) instruction interpretation; operand first to latch and only then to ALU
  - ALU output before result moved to some register

User visible registers

- Different processor families
  - different number of registers
  - different naming conventions (nimemaistavat)
  - different purposes
- General-purpose registers (yleisrekisterit)
- Data registers (datarekisterit) – not for addresses!
- Address registers (osoiterekisterit)
  - Segment registers (segmenttirekisterit)
  - Index registers (indeksirekisterit)
  - Stack pointer (pino-osottin)
  - Frame pointer (ymparistosoitin)
- Condition code registers (tilarekisterit)
  - No condition code regs.

Computer Organization II, Autumn 2010, Teemu Kerola

No condition code regs.
IA-64, MIPS
Example

Number of registers:
- 8, 16, or 32 in 1980
- RISC: several hundreds

PSW - Program Status Word
- Name varies in different architectures
- State of the CPU
  - Privileged mode vs user mode
- Result of comparison (vertailu)
  - Greater, Equal, Less, Zero, ...
- Exceptions (poikkeus) during execution?
  - Divide-by-zero, overflow
  - Page fault, "memory violation"
- Interrupt enable/ disable
- Each ‘class’ has its own bit
- Bit for interrupt request?
  - I/O device requesting guidance

Design issues:
- OS support
- memory and registers in
- control data storing
- paging
- subroutines and stacks
- etc
Instruction cycle (käskysykli)

Instruction fetch (käskyn nouto)
- MAR ← PC
- MAR ← MMU(MAR)
- Control Bus ← Reserve
- Control Bus ← Read
- PC ← ALU(PC+1)
- MBR ← MEM[MAR]
- Control Bus ← Release
- IR ← MBR

Cache (välimuisti)!
Prefetch (ennaltanouto)!

(Sta10 Fig 12.5, Sta10 Fig 12.6)
Operand fetch, Indirect addressing
(Operandin nouto, epäsuoora osoitus)

- MAR ← Address
- MAR ← MMU(MAR)
- Control Bus ← Reserve
- Control Bus ← Read
- MBR ← MEM[MAR]

- MAR ← MBR
- MAR ← MMU(MAR)
- Control Bus ← Read
- MBR ← MEM[MAR]
- Control Bus ← Release
- Cache!
- ALU? Regs? ← MBR

(Data flow, interrupt cycle)

- MAR ← SP
- MAR ← MMU(MAR)
- Control Bus ← Reserve
- MBR ← PC
- Control Bus ← Write
- MAR ← SP ← ALU(SP+1)
- MAR ← MMU(MAR)
- MBR ← PSW
- Control Bus ← Write
- SP ← ALU(SP+1)
- PSW ← privileged & disable
- MAR ← Interrupt number
- Control Bus ← Read
- PC ← MBR ← MEM[MAR]
- Control Bus ← Release

No address translation!
Instruction pipelining

(*liukuhihn*)

**Laundry example** (by David A. Patterson)

- Ann, Brian, Cathy, Dave: each have one load of clothes to wash, dry and fold
- Washer takes 30 min
- Dryer takes 40 min
- “Folder” takes 20 min
Sequential Laundry

- Takes 6 hours for 4 loads:

![Sequential Laundry Diagram]

- If they learned pipelining, how long would laundry take?

Pipelined Laundry

- Takes 3.5 hours for 4 loads

![Pipelined Laundry Diagram]

At best case, one load is completed every 40 minutes! (0.67 h / finished load)
Lessons

- Pipelining does not help latency of single task, but it helps throughput of the entire workload.
- Pipelining can delay single task compared with situation where it is alone in the system:
  - Next stage occupied, must wait.
- Multiple tasks operating simultaneously, but different phases.
- Pipeline rate limited by slowest pipeline stage:
  - Can proceed when all stages done.
  - Not very efficient, if different stages have different durations, unbalanced lengths.
- Potential speedup:
  - Maximum possible speedup.
  - Number of pipe stages.

Lessons

- Complex implementation, may need more resources.
- Enough electrical current and sockets to use both washer and dryer simultaneously.
- Two (or three) people present all the time in the laundry.
- Time to “fill” pipeline and time to “drain” it reduce speedup.
- Resources are not fully utilized.
- “Hiccups” (hikka):
  - Variation in task arrivals, works best with constant flow of tasks.
2-stage instruction execution pipeline (2-vaiheinen liukuhinna)

- Instruction prefetch (ennaltanouto) at the same time as execution of previous instruction
- Principle of locality (paikallisuus): assume ‘sequential’ execution
- Problems
  - Execution phase longer → fetch stage sometimes idle
  - Execution modifies PC (jump, branch) → fetched wrong instr.
    - Prediction of the next instruction’s location was incorrect!
- Not enough parallelism → more stages?

6-Stage (6-Phase) Pipeline

</table>

FE - Fetch instruction
DI - Decode instruction
CO - Calculate operand addresses
FO - Fetch operands
EI - Execute instruction
WO - Write operand
Pipeline speedup (nopeutus)?

- Lets calculate (based on Fig 12.10):
  - 6-stage pipeline, 9 instr. → 14 time units total
  - Same without pipeline → 9*6 = 54 time units
  - Speedup = \( \frac{\text{time}_{\text{orig}}}{\text{time}_{\text{pipeline}}} = \frac{54}{14} = 3.86 < 6 \)
  - Maximum speed at times 6-14
    - one instruction per time unit finishes
    - 8 time units → 8 instruction completions
    - Maximum speedup = \( \frac{\text{time}_{\text{orig}}}{\text{time}_{\text{pipeline}}} = \frac{48}{8} = 6 \)

- Not every instruction uses every stage
  - Will not affect the pipeline speed – some stages unused
  - Speedup may be small (some stages idle, waiting for slow)
  - Unused stage → CPU idle (execution “bubble”)
  - Serial execution could be faster (no wait for other stages)

Pipeline performance: one cycle time

\[
\tau = \max_{i=1..k} [\tau_i] + d = \tau_m + d \gg d
\]

- Cycle time is the same for all stages
  - Time (in clock pulses) to execute the stage
- Each stage takes one cycle time to execute
- Slowest stage determines the pace (tahti, etenemisvauhti)
  - The longest duration becomes bottleneck
Pipeline Speedup

n instructions, k stages, \( \tau = \text{cycle time} \)

No pipeline: \( T_1 = nk \tau \)

Pessimistic: assumes the same duration for all stages

Pipeline: \( T_k = \left[ k + (n - 1) \right] \tau \)

next (n-1) tasks (instructions) will finish each during one cycle, one after another

k stages before the first task (instruction) is finished

Speedup: \( S_k = \frac{T_1}{T_k} = \frac{nk\tau}{\left[ k + (n - 1) \right] \tau} = \frac{nk}{k + (n - 1)} \)

See Sta10 Fig 12.10 and check yourself!

Speedup vs. nr stages vs. instructions w/no jumps?

more gains from multiple stages when more instructions without jumps

(Sfa10 Fig 12.14)
Pipeline Features

- Extra issues
  - CPU must store ‘mid results’ somewhere between stages and move data from buffer to buffer
  - From one instruction’s viewpoint the pipeline takes longer time than single execution
- But still
  - Executing large set of instructions is faster
  - Better throughput (läpimenoaste) (instructions/sec)
- The parallel (concurrent) execution of instructions in the pipeline makes them proceed faster as whole, but slows down execution of single instruction

Pipeline Problems and Design Issues

- Structural dependency (rakenteellinen riippuvuus)
  - Several stages may need the same HW
  - Memory: FI, FO, WO
  - ALU: CO, EI
- Control dependency (kontrolliriippuvuus)
  - No knowledge on next instruction
  - E.g., (conditional) branch destination may be known only after EI-stage
  - → Prefetched wrong instructions
- Data dependency (datariippuvuus)
  - Instruction needs the result of the previous non-finished instruction

<table>

| ADD   | R2, R3, R4 |
| MUL   | R1, R4, R5 |

| MUL   | R1, R2, R3 |
| LOAD  | R6, Arr(R1) |
**Pipeline Dependency Problem Solutions**

- In advance: prevent (some) dependency problems completely
- At run time: Hardware must notice and wait until all dependencies are cleared
  - Add extra waits, “bubbles”, to the pipeline; Commonly used
  - Bubble (*kupla*) delays everything behind it in all stages
- Structural dependency
  - More hardware, e.g., separate ALUs for CO and EI stages
  - Lots of registers, less operands from memory
- Control dependency
  - Clear pipeline, fetch new instructions
  - Branch prediction, prefetch these or those?
- Data dependency
  - Change execution order of instructions
  - By-pass (*oikopolku*) in hardware between stages: earlier instruction’s result can be accessed already before its WO-stage is done

**Data dependency**

- **Read after Write (RAW) (a.k.a true or flow dependency)**
  - Occurs if succeeding read takes place before the preceding write operation is complete
- **Write after Read (WAR) (a.k.a antidependency)**
  - Occurs if the succeeding write operation completes before the preceding read operation takes place
- **Write after Write (WAW) (a.k.a output dependency)**
  - Occurs when the two write operations take place in the reversed order of the intended sequence
- The WAR and WAW are possible only in architectures where the instructions can finish in different order
Example: Data Dependency - RAW

Dependency: wait

MUL R1, R2, R3
ADD R4, R5, R6
SUB R7, R1, R8
ADD R1, R1, R3

Dependency: no wait

MUL R1, R2, R3
ADD R4, R5, R6
SUB R7, R1, R8
ADD R1, R1, R3

Example: Change instruction execution order

Need bubble?

MUL R1, R2, R3
ADD R4, R5, R6
SUB R7, R1, R8
ADD R9, R0, R8

No effective dependencies

MUL R1, R2, R3
ADD R4, R5, R6
ADD R9, R0, R8
SUB R7, R1, R8

Discussion?
Example: By-pass (oikopolut)

- New wires (and temp registers, latches) in pipeline
- E.g., instr. result available to FO phase directly from phase EI

With by-pass:

- New wires (and temp registers, latches) in pipeline
- E.g., instr. result available to FO phase directly from phase EI

Pipelining and Jump Optimization

- Multiple streams (Monta suorituspolkua)
- Delayed branch (Viivästetty hyppy)
- Prefetch branch target (Kohteen ennaltanouto)
- Loop buffer (Silmukkapuskun)
- Branch prediction (Ennustuslogiikka)
Effect of Conditional Branch on Pipeline

Delayed Branch (viivästetty haarautuminen)

- Compiler places some useful instructions (1 or more) after branch instructions (to delay slots)
  - Instruction in delay slots are always executed!
  - No roll-back of instructions needed due incorrect prediction
    - Rollback is difficult to do
  - If no useful instruction available, compiler uses NOP
- Less actual work lost if branch occurs
- Next instruction almost done, when branch decision known
- This is easier than emptying the pipeline during branch
- Worst case: NOP-instructions waist some cycles
- Can be difficult to do (for the compiler)
Multiple instruction streams (monta suorituspolkua)

- Execute speculatively to both directions
  - Prefetch instructions that follow the branch to the pipeline
  - Prefetch instructions from branch target to (another) pipeline
  - After branch decision: reject the incorrect pipeline (its results)

- Problems
  - Branch target address known only after some calculations
  - Second split on one of the pipelines
    - Continue any way? Only one speculation at a time?
  - More hardware!
    - More pipelines, speculative results (registers!), control
  - Speculative instructions may delay real work
    - Bus and register contention? More ALUs?
  - Capability to cancel not-taken instruction stream from pipeline
    - easier, if all changes done in WB phase

IBM 370/168, IBM 3033, Intel IA-64

Prefetch branch target (kohteen ennaltanouto)

- Prefetch just branch target instruction, but do not execute it yet
  - Do only FI-stage
  - If branch taken, no need to wait for memory
- Must be able to clear the pipeline
- Prefetching branch target may cause page-fault

IBM 360/91 (1967)
Loop buffer (sielmukkapuskuri)

- Keep \( n \) most recently fetched instructions in high speed buffer inside the CPU
- Use prefetch also
  - With good luck the branch target is in the buffer
  - F.ex. IF-THEN and IF-THEN-ELSE structures
- Works for small loops (at most \( n \) instructions)
  - Fetch from memory just once
- Gives better spacial locality than just cache

Static Branch Prediction

- Make an (educated?) guess which direction is more probable:
  Branch or no?
- Static prediction (sielmukkapuskuri)
  - Fixed: Always taken (aina hypätään)
  - Fixed: Never taken (ei koskaan hypätää)
    - ~50% correct
  - Predict by opcode (operaatiokoodin perusteella)
    - In advance decided which codes are more likely to branch
    - For example, BLE instruction is commonly used at the end of stepping loop, guess a branch
    - ~75% correct [LILJ88]
Dynamic Branch Prediction

- Dynamic prediction
  - Make a guess based on earlier history for (this) branch
  - **Logic**: What has happened in the recent history with this instruction
    - Improves the accuracy of the prediction
  - **Implementation**: extra internal memory = branch history table
    - Instruction address (for this branch)
    - Branch target (instruction or address) – need this for quick action
    - Decision: taken / not taken

- Simple prediction based on just the previous execution
  - 1 bit memory is enough
  - Loops will always have one or two incorrect predictions

2-Bit Branch Prediction Logic for One Instruction

- Improved simple model
  - Don’t change the prediction with one misprediction
  - Based on two previous executions of this instruction
  - 2 bits enough

PowerPC 620
(Stat0 Fig 12.19)
Branch Prediction History Table

Which branch instruction is this?

Prediction:
- taken/not taken

Where to jump, if branch taken

Which branch instruction is this?

Associative memory, Like cache

Pipeline basics
- Stage length, pipeline fill-up and drain times
- Response time, throughput, speedup

Hazards, dependencies
- Structural, control, data (RAW, WAR, WAW)
- How to avoid before time?
- How to handle at run time?

How to minimize branch costs?
- Delayed branch, multiple pipeline streams, prefetch branch target, loop buffer, branch prediction
Review Questions

- What information PSW needs to contain?
- Why 2-stage pipeline is not very beneficial?
- What elements effect the pipeline?
- What mechanisms can be used to handle branching?
- How does CPU move to interrupt handling?
