$$= \sum_{n_1 \in N_1} \sum_{n_2 \in N_2} \underbrace{\left( \sum_{i=1}^n I_i(T_1(n_1)) I_i(T_2(n_2)) \right)}_{\frac{\text{def} C(n_1, n_2)}{\text{def}}} \stackrel{C(\cdot, \cdot): \text{ kn. on subtrees}}{\leftarrow K(\cdot, \cdot) \text{ in conv.-kn. form}}$$

### Kernel Evaluation: Recursive Computation (I)

• Examples of admissible subtrees (tree fragments, a.-subtrees)

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

- Include the complete rule productions (prod) at the node
- · The full set of a.-subtrees need not be stored explicitly

#### Kernel Evaluation: Recursive Computation (II)

• 
$$K(T_1, T_2) = \sum_{n_1 \in N_1, n_2 \in N_2} C(n_1, n_2)$$

 $C(n_1, n_2)$ : #common a.-subtrees rooted at  $n_1, n_2$ 

• Compute *C*(*n*<sub>1</sub>, *n*<sub>2</sub>) recursively:

$$C(n_1, n_2) = \begin{cases} 0, & \operatorname{prod}(n_1) \neq \operatorname{prod}(n_2) \\ 1, & \operatorname{prod}(n_1) = \operatorname{prod}(n_2), \& n_1, n_2 \text{ pre-terminals} \end{cases}$$
$$C(n_1, n_2) = \prod_{j=1}^{nc(n_1)} \left( 1 + C\left(\frac{ch(n_1, j)}{jth \ child}, \ ch(n_2, j)\right) \right),$$
if  $\operatorname{prod}(n_1) = \operatorname{prod}(n_2), \& n_1, n_2 \text{ not pre-terminals}$ 

(recursive comp. is in part due to the definition of a.-subtrees)

Complexity of computing k(T<sub>1</sub>, T<sub>2</sub>): O(|N<sub>1</sub>||N<sub>2</sub>|), in practice, linear

#### Practical Concerns and Modifications of Kernels

• Tree size has too much effect on kernel; do normalization:

$$K'(T_1, T_2) = \frac{K(T_1, T_2)}{\sqrt{K(T_1, T_1) k(T_2, T_2)}}$$

Extreme values between similar and dissimilar trees:

$$K(T_1, T_2) \approx 10^6$$
,  $T_1 \sim T_2$ ,  $K(T_1, T_2) \approx 10$ ,  $T_1 \not\sim T_2$ 

kernel is too "peaked;" prediction will be close to "nearest neighbor" rule Solution? ("radialization" –  $\ln K$  – didn't help.)

- Modifications: downweight large a.-subtrees
  - option 1: restrict the depth of a.-subtrees; recursive evaluation is still possible by computing C(n<sub>1</sub>, n<sub>2</sub>, d)
  - option 2: scale the relative importance of a.-subtrees by their size

$$\begin{aligned} \mathcal{K}'(T_1, T_2) &= \sum_{i=1}^n \lambda^{size(s_i)} h_i(T_1) h_i(T_2) \\ \mathcal{C}(n_1, n_2) &= \lambda \prod_{j=1}^{nc(n_1)} \left( 1 + C(ch(n_1, j), ch(n_2, j)) \right) \end{aligned}$$

(ロ) (同) (三) (三) (三) (○) (○)

### Parsing Modeled as Re-ranking

- Training examples: (s<sub>i</sub>, t<sub>i</sub>), sentence and correct parse tree pairs
- Create data: input s + candidate parses, e.g.,  $C(s) = \{T_1, \ldots, T_{100}\}$
- Parse/prediction output for s:

$$\underset{T \in \mathcal{C}(\mathsf{s})}{\operatorname{arg\,max}} \, w \cdot \mathit{h}(T) = \underset{T \in \mathcal{C}(\mathsf{s})}{\operatorname{arg\,max}} \, \sum_{j} \alpha_{j} \mathit{K}(T, \widehat{T}_{j})$$

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

- Criterion for optimizing  $\alpha$ : rank  $t_i$  as the highest-score parse tree for  $s_i$
- Training algorithm: a variant of voted perceptron

### Parsing Experiments on Penn Treebank ATIS Corpus

- Treebank is randomly split (10 ways) into training (800), development (200) and test (336) sets.
- PCFG, trained on training set, produces 100 candidates for each sentence; use 20 candidates per sentence in training.
- Test: choose the best tree from the 100 candidates.
- Parse score: measure precision and recall constituent: a non-terminal label and its span
  - $c_i$ : #correctly placed constituents in the ith test tree
  - $p_i$ : #constituents proposed
  - $g_i$ : #constituents in the true parse tree

$$score = 100\% \times \frac{1}{\sum_{i} g_{i}} \sum_{i} g_{i} \times \frac{1}{2} \left( \frac{c_{i}}{p_{i}} + \frac{c_{i}}{g_{i}} \right)$$
$$rel. - improvement = 100\% \times \frac{score_{perc} - score_{PCFG}}{100 - score_{PCFG}}$$

(ロ) (同) (三) (三) (三) (○) (○)

PCFG scored 74

# Parsing Experiments on Penn Treebank ATIS Corpus (Cont'd)

Varying the maximum depth of a.-subtrees

depth	1	2	3	4	5	6
score	$73 \pm 1$	$79\pm1$	$80\pm1$	$79 \pm 1$	$79\pm1$	$78\pm0.01$
improvement	$-1\pm4$	$20\pm 6$	$23\pm3$	$21\pm4$	$19\pm4$	$18\pm3$

• Varying the scale parameter  $\lambda$  for the size of a.-subtrees

$\lambda$	0.1	0.2	0.3	0.4	0.5	0.6
score	77 ± 1	$78 \pm 1$	$79\pm1$	$79\pm1$	$79\pm1$	$79\pm1$
improvement	$11\pm6$	$17\pm5$	$20\pm4$	$21\pm3$	$21\pm4$	$22\pm4$
$\lambda$	0.7	0.8	0.9			
score	$79\pm1$	$79\pm1$	$78\pm1$			
improvement	$21\pm4$	$19\pm4$	$17\pm5$			

# Discussions

- Compact representation of f(T) = ∑<sub>j</sub> α<sub>j</sub>K(T, T̂<sub>j</sub>): find common a.-subtrees in T̂<sub>j</sub>, add weights together, and make a weighted acyclic graph
- A re-ranking model for structured prediction:

 $\underset{T \in \mathcal{T}}{\operatorname{arg\,max}} f(T)$
