Support Technologies
Contents

- Cloud computing and offloading services
- Session Initiation Protocol (SIP)
- IP Multimedia Subsystem (IMS)
- Publish/Subscribe, tuple spaces, Web services
Cloud Computing

The services of Cloud computing can be divided into three categories:

1. **Software-as-a-Service (SaaS)**, in which a vendor supplies the hardware infrastructure, the software product and interacts with the user using a portal (software on demand, pay-as-you-go).

2. **Platform-as-a-Service (PaaS)**, in which a set of software and development tools are hosted by a provider on the provider's infrastructure, for example, Google's AppEngine.

3. **Infrastructure-as-a-Service (IaaS)**, which involves virtual server instances with unique IP addresses and blocks of on-demand storage, for example, Amazon's Web services infrastructure.
Cloud Computing

Private, community, public, hybrid clouds

- Software as a Service (SaaS)
- Platform as a Service (PaaS)
- Infrastructure as a Service (IaaS)

On-demand service

- Information demand and supply (Open APIs)
- Ubiquitous Network Access
- Location Independent Resource Pooling
- Elasticity

Virtualization

Web Application Frameworks

Datacenters and clusters

Browser as a Platform
The offloading of a mobile computing task is a trade-off between the energy used for local processing and the energy required for offloading the task, uploading its data, and downloading the result, if necessary.

One can express the offloading energy trade-off as follows:
- $E_{\text{trade}} = E_{\text{local}} - E_{\text{delegate}} > 0$, where $E_{\text{local}}$ is the energy used for complete local execution, and $E_{\text{delegate}}$ is the energy used if the task is offloaded from the perspective of the mobile device.

If $E_{\text{trade}}$ is greater than zero, then there is an energy benefit for delegating the task to the cloud.
What can be offloaded?

- Content processing and transformations
  - Example: Javascript processing in OperaMini
- Completion notification and mobile push
- Application execution
  - Google docs, Windows Office
- Connection management
  - BitTorrent!
  - Large downloads
- Positioning (A-GPS)
Example of Offloading: Indexing

- Implemented with Dessy: mobile desktop search
- To offload indexing
  - Transmit entire file to the cloud service
  - Wait for response
  - Receive file summary
- High energy savings can be obtained when offloading CPU-intensive tasks
- With N900 and WLAN 700kB/s: 96.5% savings!
  - 200 000 words, 1 MB file
  - With WLAN 100kB/s this is reduced to 83.7%
Virtualization system is a framework that combines or divides computing resources to present a transparent view of one or more environments

- Hardware/software partitioning (or aggregation)
- Partial or complete machine simulation
- Emulation (can be partial or complete)
- Time-sharing
Mobile virtualization

- Server Based Virtualization of Desktop Infrastructure
  
  Moving the desktop to a virtualized image in the data center allows the complex components to be protected and componentized
    - Workload isolation and migration
    - Application virtualization

- Virtualization is a possible solution to the fragmentation problem

- http://www.vmware.com/technology/mobile/

- Virtualization for offloading
  - Running applications in a base station, nearby server, in the cloud
  - Research proposals
Session Initiation Protocol (SIP)

- An Application-layer control (signaling) protocol for creating, modifying and terminating sessions with one or more participants.
- Sessions include Internet multimedia conferences, Internet telephone calls and multimedia distribution.
- Members in a session can communicate via multicast or via a mesh of unicast relations, or a combination of these.
- Text based, model similar to HTTP.

- Current system: Signalling System 7 (SS7).
  - Circuit-switched, SIGTRAN with SCTP for IP
SIP History

- Mid-1990s, emerged from the research of Dr. Henning Schulzrinne, Columbia University, on Multi-party Multimedia Session Control (MMUSIC)
- 1996, submitted to the Internet Engineering Task Force (IETF) and developed by the SIP Working Group
- 1999, first published as IETF RFC 2543
- 2000, selected by 3GPP
- 2002, RFC 3261 (with further supplements in other RFCs)
SIP features

- User location: determination of the end system to be used for communication
- User capabilities: determination of the media and media parameters to be used
- User availability: determination of the willingness of the called party to engage in communications
- Call setup: "ringing", establishment of call parameters at both called and calling party
- Call handling: including transfer and termination of calls
State in SIP

- SIP places state in the end devices
  - End-to-end
  - If end device fails, then the session fails

- Network elements may or may not have state

- Proxies are used for discovery, forwarding, relaying
SIP messages

- Start Line (Request Line or Status Line)
  - message type (method type & URI in requests, and response code in responses)
  - protocol version

- Headers
  - fields to convey message attributes
  - can span multiple lines, appear multiple times, take multiple comma-separated values

- Body (Content)
  - to describe the session to be initiated
  - to contain opaque textual or binary data
1. SIP Addressing
2. Locating a SIP Server
3. Sending SIP Requests: SIP Transactions
4. SIP Methods
5. SIP Responses
6. Subsequent Requests and Responses
1. INVITE
   To:sip:alice@test.com

2. 100 Trying

3. DNS Query: test.com

4. Response

5. INVITE
   To:sip:bob@test.com

6. 100 Trying

7. LS Query: B?

8. Response
   SIP URI

9. INVITE
   sip:bob@test.com

10. 100 Ringing

11. 180 Ringing

12. 180 Trying

13. 200 ACK

14. 200 OK

15. OK

16. 180 ACK

User Agent Bob

Media (RTP)
The **IP Multimedia Subsystem** provides multimedia services across networks (fixed & mobile), such as:

- Instant Messaging, Video Sharing, Push-To-Talk, Gaming, Video Conferencing

IMS uses SIP protocol to setup multimedia sessions over IP network.

SIP is a signalling protocol to:

- Locate user given SIP Universal Resource Identifier (URL) (e.g., sip:jane@isp.com)
- Set up session and negotiate its parameters
IMS Proxies I

- CSCF = Call State Control Function

- A *Proxy-CSCF* (P-CSCF) is a SIP proxy that is the first point of contact for the IMS terminal
  - it is assigned to an IMS terminal during registration, and does not change for the duration of the registration
  - it sits on the path of all signalling messages, and can inspect every message
  - it authenticates the user and establishes an IPsec security association with the IMS terminal.
  - it can also compress and decompress SIP messages using SigComp, which reduces the round-trip over slow radio links
  - it may include a Policy Decision Function (PDF), which authorizes media plane resources e.g. quality of service (QoS) over the media plane. It's used for policy control, bandwidth management, etc. The PDF can also be a separate function.
  - it also generates charging records
IMS Proxies II

- A Serving-CSCF (S-CSCF) is the central node of the signalling plane
  - it is always located in the home network. It uses Diameter Cx and Dx interfaces to the HSS to download and upload user profiles — it has no local storage of the user data. All necessary information is loaded from the HSS
  - it handles SIP registrations, which allows it to bind the user location (e.g. the IP address of the terminal) and the SIP address
  - it sits on the path of all signaling messages, and can inspect every message
  - it decides to which application server(s) the SIP message will be forwarded, in order to provide their services
  - it enforces the policy of the network operator

- An Interrogating-CSCF (I-CSCF) is another SIP function located at the edge of an administrative domain

- **Push email**: Non-SIP Only Applications
Web Service Architecture

The three major roles in web services
- Service provider
  - Provider of the WS
- Service Requestor
  - Any consumer / client
- Service Registry
  - Logically centralized directory of services

A protocol stack is needed to support these roles
Web Services Protocol Stack

- **Message Transport**
  - Responsible for transporting messages
  - HTTP, BEEP

- **XML Messaging**
  - Responsible for encoding messages in common XML format
  - XML-RPC, SOAP

- **Service Description**
  - Responsible for describing an interface to a specific web service
  - WSDL

- **Service discovery**
  - Responsible for service discovery and search
  - UDDI
What is SOAP?

- Fundamentally stateless one-way message exchange paradigm
  - More complex interactions may be implemented
- Exchange of structured and typed information
  - Between peers in decentralized fashion
  - Using different mediums: HTTP, Email, ..
- Request-reply and one-way communication are supported
- Note that XML infoset is an abstract specification
  - On-the-wire representation does not have to be XML 1.0!
- SOAP 1.2 "HTTP Subset". SOAP as HTTP extension
- Specifications
  - SOAP Version 1.2 Part 0: Primer
  - SOAP Version 1.2 Part 1: Messaging Framework
  - SOAP Version 1.2 Part 2: Adjuncts
  - SOAP Version 1.2 Specification Assertions and Test Collection
REST

- REST (Representational State Transfer) (Roy Fielding, PhD thesis)
  - Architectural style of networked systems
  - Applications transfer state with each resource representation
    - Representations of the data are transmitted
  - State is a property of a resource

- Resources
  - Any addressable entity
  - Web site, HTML page, XML document, ..

- URLs Identify Resources
  - Every resource uniquely identifiable by a URI
REST II

- Uses standards
  - Addressing and naming: URI
  - Generic resource interface: HTTP GET, POST, PUT, DELETE
  - Resource representations: HTML, XML, GIF, ...
  - Media types: MIME

- Loose coupling

- Stateless transactions

- Self-descriptive messages

- Hypermedia is the engine of application state
  - Just resources and URIs
Event-based Systems and Publish/subscribe

- Event delivery from publishers to subscribers
  - Event is a message with content
  - One-to-many, many-to-many
  - Builds on messaging systems and store-and-forward

- A frequently used communication paradigm
  - Decoupling in space and time
  - Solutions from local operation to wide-area networking
  - Proposed for mobile/pervasive computing

- The event service is a logically centralized service
  - Basic primitives: subscribe, unsubscribe, publish

- Various routing topologies and semantics
Event Systems

- Traditional MoM systems are message queue based (one-to-one)
- Event systems and publish/subscribe are one-to-many or many-to-many
  - One object monitors another object
  - Reacts to changes in the object
  - Multiple objects can be notified about changes
- Events address problems with synchronous operation and polling
- In distributed environments a logically centralized service mediates events
  - anonymous communication
  - expressive semantics using filtering
Pub/Sub Service

Subscriptions

Receives notifications

Matches and sends notification to the appropriate consumers

Subscription management on behalf of the Publisher

Notifications message instances
Event Systems

- Push versus Pull
- May be implemented using RPC, unicast, multicast, broadcast,..
- Three main patterns
  - Observer design pattern
    - Used in Java / Jini
  - Notifier architectural pattern
    - Used by many research systems
  - Event channel
    - Used in CORBA Event/Notification Service
- Filtering improves scalability / accuracy
  - Research topic: content-based routing
Tuple Spaces

- Tuple-based model of coordination
- The shared tuple space is global and persistent
- Communication is
  - decoupled in space and time
  - implicit and content-based
- Primitives
  - In, atomically read and removes a tuple
  - Rd, non-destructive read
  - Out, produce a tuple
  - Eval, creates a process to evaluate tuples
- Examples: Linda, Lime, JavaSpaces, TSpaces
Java Message Service (JMS)

- Asynchronous messaging support for Java
- Point-to-point messaging
  - One-to-one
- Topic-based publish/subscribe
  - SQL for filtering messages at the topic event queue
  - One-to-many
- Message types:
  - Map, Object, Stream, Text, and Bytes
- Durable subscribers
  - Event stored at server if not deliverable
- Transactions with rollback
Client 1 Sends MSG to Queue
Queue Consumes MSG
Acknowledges MSG
Queue Delivers MSG to Client 2

Client 1 Publishes MSG to Topic
Topic Subscribes MSG from Client 2
Delivers MSG to Client 3

Topic Subscribes MSG from Client 2
Delivers MSG to Client 3
OMG Distributed Data Service

- The Data Distribution Service for Real-Time Systems (DDS)
- The specification defines an API for data-centric publish/subscribe communication for distributed real-time systems.
- DDS is a middleware service that provides a global data space that is accessible to all interested applications.
- DDS uses the combination of a Topic object and a key to uniquely identify instances of data-objects.
- Content filtering and QoS negotiation are supported
- DDS is suitable for signal, data, and event propagation.

Data synchronization
Synchronization models

- WHEN to sync?
  - manually
  - Automatically

- Synchronization and replication
  - store data in a number of locations
  - fault tolerance, but...
  - most copies unavailable most of the time
Synchronization models

- **HOW to sync?**
  - permit only one modifiable copy of data
    - lock on data
    - hub-and-spoke model
  - multiple copies can be independently modified
    - more flexible
    - more complex to implement the sync process
Synchronization models

Sync process

- Update detection
  - recognition that a data has been modified

- Update propagation
  - transmission of changes among all the data replica

- Reconciliation
  - combination of all the updated data to build a synchronized version
Synchronization models
Sync process

- Update detection
  - recognition that a data has been modified
  - triggers the start of sync process
  - clean / dirty status (modification flag)
  - modification timestamp
  - hash of the content
Synchronization models
Sync process

- Update detection
  - modification timestamp
    ✦ store only the timestamp of last modification?
      (e.g. in file system)
      - comparison of all the timestamps
        ✦ time / resource consuming!
      - monitoring file system for changes
      - use dir timestamp if equal to last modified contained file
  - semantics of modification time
    ✦ when a file timestamp is actually modified?
      ✦ content modifying, file renaming, file relocation?
Synchronization models

Sync process

- Reconciliation
  - combination of all the updated data to build a synchronized version
    - opaque data (e.g. binary, pictures)
      - ask the user which version to use
    - structured data (e.g. XML)
      - edit logs
      - state comparison
      - both (can) use the latest common ancestor as comparison aid
Synchronization models
Sync process

- Reconciliation
  - type of modifications (inside a single file):
    - insertion
    - deletion
    - moving
    - changing
  - moving often as deletion + insertion
  - use of unique ID per piece of structured content
Synchronization models
data sync algorithms & tools

- **rsync**

- **Remote Differential Compression (RDC)**
  - Microsoft Windows Server 2003 R2 / 2008
  - allows data to be synchronized between two or more computers, using compression techniques to minimize the amount of data sent across the network.
Remote Differential Compression (RDC)
- files (to be synced) divided into chunks of data
  - chunk bounded using an incremental fingerprint function
- MD4 hash calculated for each chunk
- comparison of MD4 lists (signature, one per file)
- transfer only of missing / different chunks
- can be applied recursively!
  - original file size 9GB
  - signature 81MB
  - signature of signature 6MB
Sync in middleware

- Publish / subscribe
  - for update propagation - data channel
    - each edit gets immediately published as an event
    - continuous reconciliation
    - multiple users

- for update detection
  - an update is advertised to all subscribers
Case studies: SyncML

- Synchronization Markup Language
- Open Mobile Alliance (OMA) Data Synchronization and Device Management
- Interoperable protocol to sync data
Case studies: SyncML

- Interoperable protocol to sync data
  - update propagation
    - transfer of updates among devices
  - client-server architecture
  - based on “edit log” model
    - addition, delete, replace of objects
    - unique ID
  - data type & data store independent
  - Notification of conflicts
