Course overview

Data mining, Autumn 2002, Course overview

581550-4 Data Mining (3 cu)

- Data mining, also called knowledge discovery in databases (KDD)
- In Finnish: tiedon louhinta, tietämyksen muodostaminen
- Goal of the course: an overview of pattern discovery
- Biased overview
- Theory and examples
- Course home page: http://www.cs.helsinki.fi/hannu.toivonen/teaching/timuS02/

l

Contents of the course

- Introduction
- Discovery of association rules
- Case study: discovery of episodes from telecommunications alarm databases
- Theoretical aspects of knowledge discovery
- Closed sets and formal concept analysis
- Sampling
- Search for integrity constraints in databases

Data mining, Autumn 2002, Course overview

Course organization

- lectures
 - Tuesdays and Thursdays 10-12 A414
 - 10 Sep 17 Oct
 - language of instruction: Finnish(?)
 - (discussions: Finnish or English)
- exercises
 - Tue 8-10 A320 (in English?), Fri 14-16 B450
 - 17 Sep 24 Oct
 - (a new group needed?)

Course organization (cont)

- project work
 - programming, data analysis or essays
 - acounts for appr. 1/3 of the course (1 cu)
 - detailed instructions will be given later
 - due by Fri 25 Oct

Data mining, Autumn 2002, Course overview

Course organization (cont)

- course exam: Fri 1 Nov 02, 14:00-18:00, Auditorium
- project works due: Fri 25 Oct 02
- course assistant: Taneli Mielikäinen
- project work: 0–20 points, compulsory, at least 10 points required to pass the course
- exam: 0-40 points, compulsory, at least 20 points required to pass the course
- weekly exercises: 0-10 extra points
- minimum 30/60 points, maximum 70/60 points!

Material

- course notes: Heikki Mannila and Hannu Toivonen: Knowledge Discovery in Databases: Search for Frequent Patterns
- original articles
- copies of slides
- available on the web during the course
- hardcopies available for copying in room A412

Data mining, Autumn 2002, Course overview

Background check

- prerequisities: cum laude, some mathematics
- design and analysis of algorithms (algoritmien suunnittelu ja analyysi)
- machine learning (koneoppiminen)
- approbatur or more in statistics
- probability I (todennäköisyyslaskenta I)
- database structures and algorithms (tietokannanhallinta tai tiha II)
- working on or finished a M.Sc. thesis
- looking for a M.Sc. thesis topic

Data mining activities at UH

- basic research: algorithms, theory
- applied research: genetics, ecology, ubiquitous computing, documents, natural language, ...
- FDK "From Data to Knowledge": center of excellence 2002–2007
- HIIT Basic Research Unit

Data mining, Autumn 2002, Chapter 1: Introduction

Chapter 1: Introduction

Chapter 1. Introduction

- Introduction
- What is KDD?
- Two examples
- Data mining vs. statistics and machine learning
- Data mining and databases

Data mining, Autumn 2002, Chapter 1: Introduction

What is data mining?

Goal: obtain useful knowledge from large masses of data.

- "Tell something interesting about this data."
- "Describe this data."
- exploratory data analysis on large data sets

Examples of discovered knowledge

• association rules:

"80 % of customers who buy beer and sausage buy also mustard"

- \bullet rules: "if Age < 40 then Income < 10"
- functional dependencies:

$$A \to B$$
, i.e., "if $t[A] = u[A]$, then $t[B] = u[B]$ "

- belief networks
- clusterings

Data mining, Autumn 2002, Chapter 1: Introduction

Example: sales data

- ullet 0/1 matrix D
- rows:customers
- columns: products
- $\bullet \ t(A) = \mathbf{1} \ \mathrm{iff} \ \mathrm{customer} \ t \ \mathrm{bought} \ \mathrm{product} \ A$
- thousands of products, millions of rows
- easy to collect
- find something interesting from this?

Association rules

- mustard, sausage, beer ⇒ chips
- conditional probability (confidence) of the rule: 0.8
- frequency of the rule: 0.2
- arbitrary number of conjuncts on the left-hand side

Find all association rules with frequency at least *min_fr*.

Data mining, Autumn 2002, Chapter 1: Introduction

Example: student/course data

 \bullet matrix D with D(t,c)=1 iff student t has taken course c

Example: student/course data

• example rule:

```
if {Data Communications, Unix, Networks}
then (graduation) (0.3)
```

Data mining, Autumn 2002, Chapter 1: Introduction

Example: SKICAT sky survey

approximately 1000 photographs of 13000x13000 pixels

- $\Rightarrow 3 \cdot 10^9$ smudges of light, each with 40 attributes
 - task 1: classify the objects to
 - stars
 - galaxies
 - others
 - task 2: find some interesting clusters of objects
 - quasars with high redshift
 - ...

machine learning? pattern recognition?

Why data mining?

- raw data is easy to collect, expensive to analyze
- more data than can be analyzed using traditional methods
- suspicion that important knowledge could be there
- successful applications
- methods: machine learning, statistics, databases
- a tool for exploratory data analysis
- can and has to be used in combination with traditional methods
- strong interest from 1989-, hype from 1995-

Data mining, Autumn 2002, Chapter 1: Introduction

The KDD process

- understanding the domain,
- preparing the data set,
- discovering patterns (data mining),
- postprocessing of discovered patterns, and
- putting the results into use

Where is the effort?

iteration, interaction

Data mining vs. data warehousing and OLAP

Very briefly:

- data warehousing makes data mining a lot cheaper
- data mining is one of the reasons for data warehousing
- OLAP: verification-driven
- data mining: discovery-driven
- MIS (management information systems)

Data mining, Autumn 2002, Chapter 1: Introduction

Data mining and related areas

Possible comments:

- That's just machine learning!
- That's just statistics!
- What has that to do with databases?

Data mining vs. machine learning

- machine learning methods are used for data mining
 - classification, clustering, ...
- amount of data makes a difference
 - accessing examples can be a problem
- data mining has more modest goals:
 - automating tedious discovery tasks, not aiming at human performance in real discovery
 - helping user, not replacing them
- this course: data mining \ machine learning

Data mining, Autumn 2002, Chapter 1: Introduction

Data mining vs. statistics

"tell me something interesting about this data" – what else is this than statistics?

- the goal is similar
- different types of methods
- in data mining one investigates a lot of possible hypotheses
- amount of data
- data mining as a preliminary stage for statistical analysis
- challenge to data mining: better contact with statistics

 22

Data mining and databases

- ordinary database usage: deductive
- knowledge discovery: inductive
- new challenges for database vendors
- parts of databases techniques are not very relevant
 - transaction management
 - recovery

Data mining, Autumn 2002, Chapter 1: Introduction

Database research for data mining I

- making it possible to run data mining algorithms on very large databases
- modified learning algorithms
 - minimize number of passes through the data
 - modify access routes
 - ...
- data servers: architectures, algorithms, data structures, memory management
- primitive operations inside a DBMS
- several data mining applications use currently very little of what is known about efficient access structures

 24

Database research for data mining II

- "Inductive databases"
- why was the relational model so successful?
 - ad hoc queries
- the same is needed for data mining
- high-level query languages for data mining applications
- query processing and optimization for such languages
- not easy
- Imielinski & Mannila: A database perspective on knowledge discovery, CACM November 1996.

Data mining, Autumn 2002, Chapter 1: Introduction

Example: episodes in sequences

- Data: events in time, e.g.,
 - alarms in telecommunications networks
 - user actions in an user interface
 - database transactions
 - biostatistical events
- Goals: understanding the structure of the process producing the events, prediction of future events.
- How to discover which combinations of events occur frequently?

 26

Example sequence

EDF A BCEF C D BAD C EFC BEAECF

D → time

Observations:

- whenever E occurs, F occurs soon
- whenever A and B occur (in either order), C occurs soon

Data mining, Autumn 2002, Chapter 1: Introduction

28

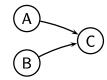

Telecommunications alarm log

Event	Time	
KE82K02-31	780560888	
KE82K10-16	780560892	
H-M-K09-57	780560917	100–400 different events
SOT-K01-03	780560926	events occur recurrently 1 month = 70 000 alarms
MUU-K03-04	780561011	1 months
KE82K10-16	780561015	
PAK-K14-27	780561119	
KE82K10-16	780561138	

Sequences and episodes

Data a sequence of (event, time) pairs (A, 123), (B, 125), (D, 140), (A, 150), (C, 151), (D, 201), (A, 220)

Patterns episodes: a set of events
occurring close to each other in time
in an order extending a given partial order

Data mining, Autumn 2002, Chapter 1: Introduction

 ${\bf Pattern~class~All~serial~episodes~/~all~parallel~episodes~/~all~episodes~/~...}$

 $\begin{array}{c} \textbf{Occurrence} \ \ \text{pattern occurs frequently in data if there are sufficiently} \\ \ \ \text{many windows of size } W \ \ \text{in the data such that the pattern occurs} \\ \ \ \text{in the window} \\ \end{array}$

Discovering frequent patterns

- find all frequent episodes of size 1
- build candidate episodes of size 2
- check which episodes of size 2 occur frequently
- continue
- incremental recognition, using previous rounds of computation, ...

Data mining, Autumn 2002, Chapter 1: Introduction

A general model for data mining

- given a class of patterns
- an occurrence criterion
- find all patterns from the class that occur frequently enough

Why is data mining fun?

- practically relevant
- easy theoretical questions
- the whole spectrum: from theoretical issues to systems issues to concrete data cleaning to novel discoveries
- easy to cooperate with other areas and with industry

Data mining, Autumn 2002, Chapter 2: Association rules

Chapter 2: Association rules

Chapter 2. Association rules

- 1. Problem formulation
- 2. Rules from frequent sets
- 3. Finding frequent sets
- 4. Experimental results
- 5. Related issues
- 6. Rule selection and presentation
- 7. Theoretical results

Data mining, Autumn 2002, Chapter 2: Association rules

Example

- Customer 1: mustard, sausage, beer, chips
 - Customer 2: sausage, ketchup
 - Customer 3: beer, chips, cigarettes

. . .

Customer 236513: coke, chips

- beer \Rightarrow chips
 - confidence (conditional probability): 0.87
 - frequency (support): 0.34

Problem formulation: data

- ullet a set R of items
- $\bullet\,$ a $\textit{0/1 relation }r\,$ over R is a collection (or multiset) of subsets of R
- ullet the elements of r are called rows
- ullet the number of rows in r is denoted by |r|
- \bullet the size of r is denoted by $||r|| = \sum_{t \in r} |t|$

Data mining, Autumn 2002, Chapter 2: Association rules

Row ID	Row
t_1	$\{A,B,C,D,G\}$
t_2	$\{A,B,E,F\}$
t_3	$\{B,I,K\}$
t_4	$\{A,B,H\}$
t_5	$\{E,G,J\}$

Figure 1: An example 0/1 relation r over the set $R=\{A,\ldots,K\}.$

Patterns: sets of items

- ullet r a 0/1 relation over R
- $X \subseteq R$
- ullet X matches a row $t \in r$, if $X \subseteq t$
- ullet the set of rows in r matched by X is denoted by $\mathcal{M}(X,r)$, i.e., $\mathcal{M}(X,r)=\{t\in r\ \big|\ X\subseteq t\}.$
- the (relative) frequency of X in r, denoted by fr(X, r), is

$$rac{|\mathcal{M}(X,r)|}{|r|}.$$

ullet Given a frequency threshold min_fr $\in [0,1]$, the set X is frequent, if $\mathit{fr}(X,r) \geq \mathit{min_fr}$.

Data mining, Autumn 2002, Chapter 2: Association rules

Example

Row ID	А	В	С	D	Е	F	G	Н	I	J	K
t_1	1	1	1	1	0	0	1	0	0	0	0
t_2	1	1	0	0	1	1	0	0	0	0	0
t_3	0	1	0	0	0	0	0	0	1	0	1
t_4	1	1	0	0	0	0	0	1	0	0	0
t_5	0	0	0	0	1	0	1	0	0	1	0

- a 0/1 relation over the schema $\{A,\ldots,K\}$
 - $fr({A,B},r) = 3/5 = 0.6$
 - $\mathcal{M}(\{A,B\},r) = \{t_1,t_2,t_4\}$

Frequent sets

- given R (a set), r (a 0/1 relation over R), and min_fr (a frequency threshold)
- the collection of frequent sets $\mathcal{F}(r, min_fr)$

$$\mathcal{F}(r, \min_{f} r) = \{X \subseteq R \mid fr(X, r) \geq \min_{f} r\},\$$

• In the example relation:

$$\mathcal{F}(r,0.3) = \{\emptyset, \{A\}, \{B\}, \{E\}, \{G\}, \{A,B\}\}$$

Data mining, Autumn 2002, Chapter 2: Association rules

Association rules

- ullet Let R be a set, r a 0/1 relation over R, and $X,Y\subseteq R$ sets of items
- $X \Rightarrow Y$ is an association rule over r.
- The *confidence* of $X\Rightarrow Y$ in r, denoted by $conf(X\Rightarrow Y,r)$, is $\frac{|\mathcal{M}(X\cup Y,r)|}{|\mathcal{M}(X,r)|}.$
 - The confidence $conf(X\Rightarrow Y,r)$ is the conditional probability that a row in r matches Y given that it matches X

Association rules II

- ullet The frequency $\mathit{fr}(X\Rightarrow Y,r)$ of $X\Rightarrow Y$ in r is $\mathit{fr}(X\cup Y,r)$.
 - frequency is also called support
- a frequency threshold min_fr and a confidence threshold min_conf
- $X\Rightarrow Y$ holds in r if and only if $\mathit{fr}(X\Rightarrow Y,r)\geq \mathit{min_fr}$ and $\mathit{conf}(X\Rightarrow Y,r)\geq \mathit{min_conf}.$

Data mining, Autumn 2002, Chapter 2: Association rules

Discovery task

- given R, r, min_fr, and min_conf
- ullet find all association rules $X\Rightarrow Y$ that hold in r with respect to min_fr and min_conf
- ullet X and Y are disjoint and non-empty
- $min_fr = 0.3$, $min_conf = 0.9$
- ullet The only association rule with disjoint and non-empty left and right-hand sides that holds in the database is $\{A\} \Rightarrow \{B\}$
- frequency 0.6, confidence 1
- when is the task feasible?

How to find association rules

- Find all frequent item sets $X \subseteq R$ and their frequencies.
- Then test separately for all $Y\subset X$ with $Y\neq\emptyset$ whether the rule $X\setminus Y\Rightarrow Y$ holds with sufficient confidence.
- Latter task is easy.
- exercise: rule discovery and finding frequent sets are equivalent problems

Data mining, Autumn 2002, Chapter 2: Association rules

Rule generation

Algorithm

Input: A set R, a 0/1 relation r over R, a frequency threshold min_fr , and a confidence threshold min_conf .

Output: The association rules that hold in r with respect to min_fr and min_conf , and their frequencies and confidences.

```
\label{eq:method:} \begin{array}{ll} \text{Method:} \\ 1. & // \text{ Find frequent sets (Algorithm 50):} \\ 2. & \text{compute } \mathcal{F}(r, \textit{min\_fr}) := \{X \subseteq R \mid \textit{fr}(X, r) \geq \textit{min\_fr}\}; \\ 3. & // \text{ Generate rules:} \\ 4. & \text{for all } X \in \mathcal{F}(r, \textit{min\_fr}) \text{ do} \\ 5. & \text{for all } Y \subset X \text{ with } Y \neq \emptyset \text{ do} \\ 6. & \text{if } \textit{fr}(X)/\textit{fr}(X \setminus Y) \geq \textit{min\_conf then} \\ 7. & \text{output the rule } X \setminus Y \Rightarrow Y, \textit{fr}(X), \textit{ and } \textit{fr}(X)/\textit{fr}(X \setminus Y); \\ \end{array}
```

Correctness and running time

- the algorithm is correct
- running time?

Data mining, Autumn 2002, Chapter 2: Association rules

Finding frequent sets: reasoning behind Apriori

- ullet trivial solution: look at all subsets of R
- not feasible
- iterative approach
- first frequent sets of size 1, then of size 2, etc.
- ullet a collection \mathcal{C}_l of candidate sets of size l
- ullet then obtain the collection $\mathcal{F}_l(r)$ of frequent sets by computing the frequencies of the candidates from the database
- minimize the number of candidates?

- ullet monotonicity: assume $Y\subseteq X$
- ullet then $\mathcal{M}(Y)\supseteq\mathcal{M}(X)$, and $\mathit{fr}(Y)\geq\mathit{fr}(X)$
- ullet if X is frequent then Y is also frequent
- Let $X \subseteq R$ be a set. If any of the proper subsets $Y \subset X$ is not frequent then (1) X is not frequent and (2) there is a non-frequent subset $Z \subset X$ of size |X| 1.

Data mining, Autumn 2002, Chapter 2: Association rules

Example

$$\mathcal{F}_2(r) = \{\{A,B\}, \{A,C\}, \{A,E\}, \{A,F\}, \{B,C\}, \{B,E\}, \{C,G\}\},$$

- \bullet then $\{A,B,C\}$ and $\{A,B,E\}$ are the only possible members of $\mathcal{F}_3(r)$,
- levelwise search: generate and test
- candidate collection:

$$\mathcal{C}(\mathcal{F}_l(r))=\{X\subseteq Rig|X|=l{+}1 ext{ and } Y\in \mathcal{F}_l(r) ext{ for all } Y\subseteq X, |Y|=l$$

Apriori algorithm for frequent sets

Algorithm

Input: A set R, a 0/1 relation r over R, and a frequency threshold min_fr .

Output: The collection $\mathcal{F}(r, min_fr)$ of frequent sets and their frequencies.

```
\label{eq:Method:} \begin{split} \mathbf{Method:} & 1. \quad \mathcal{C}_1 := \{\{A\} \mid A \in R\}; \\ 2. \quad l := 1; \\ 3. \quad \mathbf{while} \ \mathcal{C}_l \neq \emptyset \ \mathbf{do} \\ 4. \qquad // \ \  \  \text{Database pass (Algorithm 57):} \\ 5. \qquad & \text{compute} \ \mathcal{F}_l(r) := \{X \in \mathcal{C}_l \mid \textit{fr}(X,r) \geq \textit{min\_fr}\}; \\ 6. \qquad l := l+1; \\ 7. \qquad // \ \  \  \text{Candidate generation (Algorithm 54):} \\ 8. \qquad & \text{compute} \ \mathcal{C}_l := \mathcal{C}(\mathcal{F}_{l-1}(r)); \\ 9. \qquad & \text{for all } l \ \text{and for all } X \in \mathcal{F}_l(r) \ \mathbf{do} \ \text{output } X \ \text{and } \textit{fr}(X,r); \end{split}
```

Data mining, Autumn 2002, Chapter 2: Association rules

Correctness

- reasonably clear
- optimality in a sense?
- For any collection $\mathcal S$ of subsets of X of size l, there exists a 0/1 relation r over R and a frequency threshold $\min_{-} fr$ such that $\mathcal F_l(r) = \mathcal S$ and $\mathcal F_{l+1}(r) = \mathcal C(\mathcal S)$.
- fewer candidates do not suffice

Additional information can change things...

- frequent sets: $\{A,B\}$, $\{A,C\}$, $\{A,D\}$, $\{B,C\}$, and $\{B,D\}$
- ullet candidates: $\{A,B,C\}$ and $\{A,B,D\}$
- what if we know that $fr(\{A,B,C\}) = fr(\{A,B\})$
- $\bullet \ \, {\rm can \ infer} \, \, \mathit{fr}(\{A,B,D\}) < \mathit{min_fr} \\$
- how?

Data mining, Autumn 2002, Chapter 2: Association rules

Candidate generation

- ullet how to generate the collection $\mathcal{C}(\mathcal{F}_l(r))$?
- trivial method: check all subsets
- ullet compute potential candidates as unions $X \cup Y$ of size l+1
- ullet here X and Y are frequent sets of size l
- check which are true candidates
- not optimal, but fast
- collections of item sets are stored as arrays, sorted in the lexicographical order

Candidate generation algorithm

Algorithm

Input: A lexicographically sorted array $\mathcal{F}_l(r)$ of frequent sets of size l.

Output: $C(\mathcal{F}_l(r))$ in lexicographical order.

Method:

- 1. for all $X \in \mathcal{F}_l(r)$ do
- 3. for all $Z \subset (X \cup Y)$ such that $|Z| = l \ \mathbf{do}$
- 4. if Z is not in $\mathcal{F}_l(r)$ then continue with the next Y at line 2;
- 5. output $X \cup Y$;

Data mining, Autumn 2002, Chapter 2: Association rules

Correctness and running time

Theorem 1 Algorithm 54 works correctly.

Theorem 2 Algorithm 54 can be implemented to run in time $\mathcal{O}(l^2 |\mathcal{F}_l(r)|^2 \log |\mathcal{F}_l(r)|)$.

Optimizations

compute many levels of candidates at a single pass

$$\mathcal{F}_2(r) = \{\{A, B\}, \{A, C\}, \{A, D\}, \{A, E\}, \{B, C\}, \{B, D\}, \{B, G\}, \{C, D\}, \{F, G\}\}.$$

$$\begin{array}{rcl} \mathcal{C}(\mathcal{F}_2(r)) & = & \{\{A,B,C\},\{A,B,D\},\{A,C,D\},\{B,C,D\}\}, \\ \mathcal{C}(\mathcal{C}(\mathcal{F}_2(r))) & = & \{\{A,B,C,D\}\}, \text{ and} \\ \mathcal{C}(\mathcal{C}(\mathcal{C}(\mathcal{F}_2(r)))) & = & \emptyset. \end{array}$$

Data mining, Autumn 2002, Chapter 2: Association rules

Database pass

- go through the database once and compute the frequencies of each candidate
- thousands of candidates, millions of rows

Algorithm **Input:** R, r over R, a candidate collection $C_l \supseteq \mathcal{F}_l(r, min_fr)$, and min_fr . **Output:** Collection $\mathcal{F}_l(r, min_fr)$ of frequent sets and frequencies. Method: // Initialization: for all $A \in R$ do $A.is_contained_in := \emptyset$; for all $X \in \mathcal{C}_l$ and for all $A \in X$ do $A.is_contained_in := A.is_contained_in \cup \{X\};$ 5. for all $X \in \mathcal{C}_l$ do X.freq_count := 0; 6. // Database access: for all $t \in r$ do 7. for all $X \in C_l$ do $X.item_count := 0$; 8. 9. for all $A \in t$ do for all $X \in A$.is_contained_in do 10 $X.item_count := X.item_count + 1;$ 11. 12 if $X.item_count = l$ then $X.freq_count := X.freq_count + 1$; // Output: 13 for all $X \in \mathcal{C}_l$ do 14. 15 if $X.freq_count/|r| \ge min_fr$ then output X and $X.freq_count/|r|$;

Data mining, Autumn 2002, Chapter 2: Association rules

Data structures

- \bullet for each $A \in R$ a list $A.\textit{is_contained_in}$ of candidates that contain A
- ullet For each candidate X we maintain two counters:
 - $-X.freq_count$ the number of rows that X matches,
 - X.item_count the number of items of X

Correctness

• clear (?)

Time complexity

• $\mathcal{O}(||r|| + l |r| |\mathcal{C}_l| + |R|)$

Data mining, Autumn 2002, Chapter 2: Association rules

Experimental results

- small course registration database
- 4 734 students
- 127 courses
- frequency thresholds 0.01–0.2

Size	Frequency threshold							
	0.200	0.100	0.075	0.050	0.025	0.010

and time used for set of different sizes								

Number of sets

Extensions

- candidate generation
- rule generation
- database pass
 - inverted structures
 - Partition method
 - hashing to determine which candidates match a row or to prune candidates
- item hierarchies
- attributes with continuous values

Data mining, Autumn 2002, Chapter 2: Association rules

Rule selection and presentation

- recall the KDD process
- association rules etc.: idea is to generate all rules of a given form
- lots of rules
- all rules won't be interesting
- how to make it possible for the user to find the truly interesting rules?
- second-order knowledge discovery problem
- provide tools for the user

Uninteresting rules

- There are 2010 association rules in the course enrollment database that match at least 11 students (i.e., the frequency (or support) threshold is 0.01).
- prior knowledge: Design and Analysis of Algorithms ⇒ Introduction to Computers (0.97, 0.03).
- uninteresting attributes or attribute combinations. Introduction to Computers

 Programming in Pascal (0.95, 0.60) is useless, if the user is only interested in graduate courses.
- Rules can be redundant. Data Communications, Programming in C ⇒ Unix Platform (0.14, 0.03) and Data Communications, Programming in C, Introduction to Unix ⇒ Unix Platform (0.14, 0.03).

Data mining, Autumn 2002, Chapter 2: Association rules

Iteration

- filter out rules referring to uninteresting courses
- all rules containing basic courses away: only half are left
- focus to, e.g., all rules containing the course "Programming in C"
- filter out "Unix Platform"
- etc.

Operations

- pruning: reduction of the number of rules;
- ordering: sorting of rules according, e.g., to statistical significance; and
- structuring: organization of the rules, e.g., to clusters or hierarchies.
- other operations?

Data mining, Autumn 2002, Chapter 2: Association rules

Pruning using templates

- hierarchies among attributes $\{Artificial\ Intelligence,\ Programming\ in\ C,\ Data\ Communications\}\subset Undergraduate\ Course \subset Any Course,$
- ullet a template is an expression $A_1,\ldots,A_k\Rightarrow A_{k+1},\ldots,A_l$,
- ullet A_i : an attribute name, a class name, or an expression C+ or C*
- ullet Graduate Course, Any Course* \Rightarrow Design and Analysis of Algorithms
- selective/unselective template

Theoretical analyses

- fairly good algorithm
- is a better one possible?
- how good will this algorithm be on future data sets
- a lower bound (skipped)
- association rules on random data sets (skipped)
- sampling

Data mining, Autumn 2002, Chapter 2: Association rules

Sampling for finding association rules

- two causes for complexity
- lots of attributes
- lots of rows
- potentially exponential in the number of attributes
- linear in the number of rows
- too many rows: take a sample from them
- in detail later

Chapter 3: Alarm correlation

Data mining, Autumn 2002, Chapter 3: Alarm correlation

Part II. Episodes in sequences

- Chapter 3: Alarm correlation
- Chapter 4: Frequent episodes
- Chapter 5: Minimal occurrences of episodes
- Chapter 6: Episode discovery process

3. Alarm correlation: networks and alarms

- network elements: switches, base stations, transmission equipment, etc.
- 10–1000 elements in a network
- an alarm: a message generated by a network element

 1234 EL1 BTS 940926 082623 A1 Channel missing
- hundreds of different alarm types
- 200 10000 alarms a day
- each contains only local information

Data mining, Autumn 2002, Chapter 3: Alarm correlation

Characteristics of the alarm flow

- a variety of situations
- bursts of alarms
- hardware and software change fast

Alarm correlation

"correlating" alarms: combining the fragmented information contained in the alarm sequence and interpreting the whole flow of alarms

- removing redundant alarms
- filtering out low-priority alarms
- replacing alarms by something else
- systems exist
 - knowledge base (correlation rules) constructed manually
 - look at the alarms occurring in a given time window
 - apply actions given in the matching correlation rules

Data mining, Autumn 2002, Chapter 3: Alarm correlation

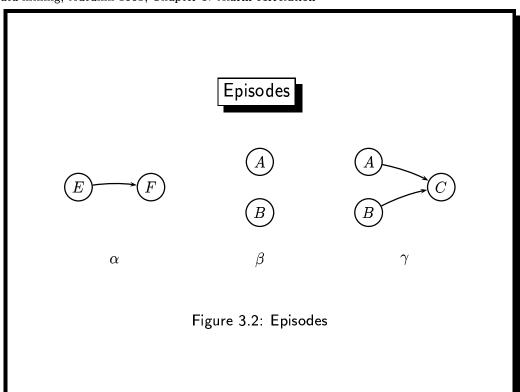

Problem

- how to obtain the information needed for the preparation of an alarm correlation system
- more generally: how to obtain insight into the behavior of the network (alarms)

Solutions

- how to analyze a flow of alarms?
- lots of possibilities: hazard models, neural networks, rule-based representations
- comprehensibility of the discovered knowledge
- simple rule-based representations
- "if certain alarms occur within a time window, then a certain alarm will also occur"

Data mining, Autumn 2002, Chapter 3: Alarm correlation

Basic solution

- look for repeated occurrences of episodes in the alarm flow sequences
- occurrence: alarms of the specified type occur in the specified order
- why this form?
 - comprehensible
 - "standard" for correlation systems
 - represent simple causal relationships
 - insensitive to inaccurate clocks
 - allows analysis of merged, unrelated sequences

Data mining, Autumn 2002, Chapter 4: Episodes

Chapter 4: Episodes

4. Frequent episodes

- The framework
- Algorithms
- Experiments

Data mining, Autumn 2002, Chapter 4: Episodes

A D

time

Example sequence

EDF A BCEF C D BAD C EFC BEAECF

Figure 3.1: A sequence of alarms

Observations:

- whenever E occurs, F occurs soon
- whenever A and B occur (in either order), C occurs soon

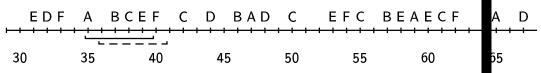

- ullet a set R of event types
- ullet an event is a pair (A,t)
- ullet $A\in R$ is an event type
- t is an integer, the (occurrence) time of the event
- event sequence s on R: a triple (s, T_s, T_e)
- ullet $T_s < T_e$ are integer (starting and ending time)
- $s = \langle (A_1, t_1), (A_2, t_2), \dots, (A_n, t_n) \rangle$
- $\bullet \ \ A_i \in R \ \text{and} \ T_s \leq t_i < T_e \ \text{for all} \ i=1,\dots,n$
- $t_i \leq t_{i+1}$ for all $i = 1, \ldots, n-1$

Data mining, Autumn 2002, Chapter 4: Episodes

85

Example

4.1: The example event sequence s and two windows of width 5.

Figure

Windows

- ullet event sequence $\mathbf{s}=(s,T_s,T_e)$
- ullet a window on it: $\mathbf{w} = (w, t_s, t_e)$
- $\bullet \ t_s < T_e, t_e > T_s$
- ullet w consists of those pairs (A,t) from s where $t_s \leq t < t_e$
- $width(\mathbf{w}) = t_e t_s$: the width of the window \mathbf{w}
- ullet $\mathcal{W}(\mathbf{s},\textit{win})$: all windows \mathbf{w} on \mathbf{s} such that $width(\mathbf{w}) = \textit{win}$
- first and last windows!

Data mining, Autumn 2002, Chapter 4: Episodes

Episodes

- an episode α is a triple (V, \leq, g)
- ullet V is a set of nodes
- $\bullet \ \le {\sf is \ a \ partial \ order \ on} \ V$
- ullet g:V
 ightarrow R is a mapping associating each node with an event type
- ullet intuition: the events in g(V) have to occur in the order described by \leq
- ullet size of lpha, denoted |lpha|, is |V|
- ullet parallel episode: the partial order \leq is trivial
- \bullet serial episode: \leq is a total order
- injective: no event type occurs twice in the episode

 α

Figure 4.2: An episode

the set V, the mapping g

Data mining, Autumn 2002, Chapter 4: Episodes

Example, subepisode

 \overline{R}

 β

 γ

Figure 4.3: A subepisode and episode

Subepisodes

 $\beta=(V',\leq',g') \text{ is a } \textit{subepisode} \text{ of } \alpha=(V,\leq,g), \ \beta \preceq \alpha, \text{ if:}$ there exists an injective mapping $f:V' \to V$ such that

- $\bullet \ g'(v) = g(f(v)) \ \text{for all} \ v \in V'$
- ullet for all $v,w\in V'$ with $v\leq' w$ also $f(v)\leq f(w)$

An episode α is a *superepisode* of β if and only if $\beta \preceq \alpha$ $\beta \prec \alpha$ if $\beta \preceq \alpha$ and $\alpha \not\preceq \beta$

In the example: $\beta \leq \gamma$

Data mining, Autumn 2002, Chapter 4: Episodes

91

Occurrences of episodes

 $lpha=(V,\leq,g)$ occurs in an event sequence $\mathbf{s}=\left(\left\langle (A_1,t_1),(A_2,t_2),\ldots,(A_n,t_n)\right
angle,T_s,T_e\right)$, if there exists an injective mapping $h:V\to\{1,\ldots,n\}$ from nodes to events, such that

- $\bullet \ \ g(x) = A_{h(x)} \ \text{for all} \ x \in V$
- ullet for all $x,y\in V$ with x
 eq y and $x\leq y$ we have $t_{h(x)}< t_{h(y)}$ (or h(x)< h(y))

(w,35,40) on the example sequence: events of types $A,\,B,\,C,$ and E both β and γ occur

Frequency of occurrence

ullet the frequency of an episode lpha in ${f s}$ is

$$\mathit{fr}(lpha,\mathbf{s},\mathit{win}) = rac{|\{\mathbf{w} \in \mathcal{W}(\mathbf{s},\mathit{win}) \mid lpha \; \mathsf{occurs \; in \; } \mathbf{w}\}|}{|\mathcal{W}(\mathbf{s},\mathit{win})|},$$

- ullet i.e., the fraction of windows on ${f s}$ in which lpha occurs.
- a frequency threshold min_fr
- α is frequent if $fr(\alpha, \mathbf{s}, win) \geq min_fr$
- $\mathcal{F}(s, win, min_fr)$: collection of frequent episodes in s with respect to win and min_fr
- size = l: $\mathcal{F}_l(\mathbf{s}, \textit{win}, \textit{min_fr})$.

Data mining, Autumn 2002, Chapter 4: Episodes

Pattern discovery task

given an event sequence s, a set \mathcal{E} of episodes, a window width win, and a frequency threshold min_fr , find $\mathcal{F}(s, win, min_fr)$

Algorithms

Algorithm 4.13

Input: A set R of event types, an event sequence ${\bf s}$ over R, a set ${\cal E}$ of episodes, a window width win, and a frequency threshold min_fr.

Output: The collection $\mathcal{F}(\mathbf{s}, win, min_fr)$ of frequent episodes.

Method: 1 comp

- compute $\mathcal{C}_1:=\{lpha\in\mathcal{E}\;ig|\; |lpha|=1\};$
- 2. l := 1;
- while $C_l \neq \emptyset$ do
- // Database pass (Algorithms 4.19 and 4.21):
- compute $\mathcal{F}_l(\mathbf{s}, win, min_fr) := \{\alpha \in \mathcal{C}_l \mid fr(\alpha, \mathbf{s}, win) \geq min_fr\};$
- l := l + 1;
- 7. // Candidate generation (Algorithm 4.14):
- compute $C_l:=\{lpha\in\mathcal{E}\mid |lpha|=l, \text{ and } eta\in\mathcal{F}_{|eta|}(\mathbf{s},\textit{win},\textit{min_fr}) \text{ for all }$ $\beta \in \mathcal{E}$ such that $\beta \prec \alpha$ and $|\beta| < l\}$;
- for all l do output $\mathcal{F}_l(\mathbf{s}, win, min_fr)$;

Data mining, Autumn 2002, Chapter 4: Episodes

95

Basic lemma, once again

Lemma 4.12 If an episode α is frequent in an event sequence s, then all subepisodes $\beta \leq \alpha$ are frequent.

Parallel, serial, injective episodes

- parallel episode: the partial order ≤ is trivial
 (= frequent sets)
- serial episode: ≤ is a total order
 (= frequent subsequence)
- *injective*: no event type occurs twice in the episode (= proper sets, not multi sets)
- useful cases: (serial or parallel) [injective] episodes
 - reduce redundancy in generated episodes
 - keep episodes comprehensible
 - simpler to implement

Data mining, Autumn 2002, Chapter 4: Episodes

Generation of candidate episodes

- parallel episodes, serial episodes (injective or non-injective)
- same idea as for association rules
- a candidate episode has to be a combination of two episodes of smaller size
- very small variations to the candidate generation procedure

Recognizing episodes in sequences

- first problem: given a sequence and an episode, find out whether the episode occurs in the sequence
- finding the number of windows containing an occurrence of the episode can be reduced to this
- successive windows have a lot in common
- how to use this?
- an incremental algorithm

Data mining, Autumn 2002, Chapter 4: Episodes

Parallel episodes

- for each candidate α maintain a counter $\alpha.event_count$: how many events of α are present in the window
- When $\alpha.event_count$ becomes equal to $|\alpha|$, indicating that α is entirely included in the window
 - save the starting time of the window in $\alpha.inwindow$
- when $\alpha.event_count$ decreases again, increase the field $\alpha.freq_count$ by the number of windows where α remained entirely in the window

Serial episodes

- use state automata that accept the candidate episodes
- example: episode A B A B

General episodes

different alternatives

Data mining, Autumn 2002, Chapter 4: Episodes

	Ir		Inj	ective
Window	Serial episodes		parallel episodes	
width (s)	Count	Time (s)	Count	Time (s)
10	16	31	10	8
20	31	63	17	9
40	57	117	33	14
60	87	186	56	15
80	145	271	95	21
100	245	372	139	21
120	359	478	189	22

9	$1 \cdot 10^{22}$	1.7	1.4	83 %
10-		17.4	16.0	92 %

Table 4.3: Number of candidate and frequent serial episodes in \mathbf{s}_1 with frequency threshold 0.003 and averaged over window widths 10, 20, 40, 60, 80, 100, and 120 s

Experiences in alarm correlation

Useful in

- finding long-term, rather frequently occurring dependencies,
- creating an overview of a short-term alarm sequence, and
- evaluating the consistency and correctness of alarm databases
- discovered rules have been applied in alarm correlation
- lots of rules are trivial

Data mining, Autumn 2002, Chapter 5: Minimal occurrences of episodes6

Chapter 5: Minimal occurrences of episodes

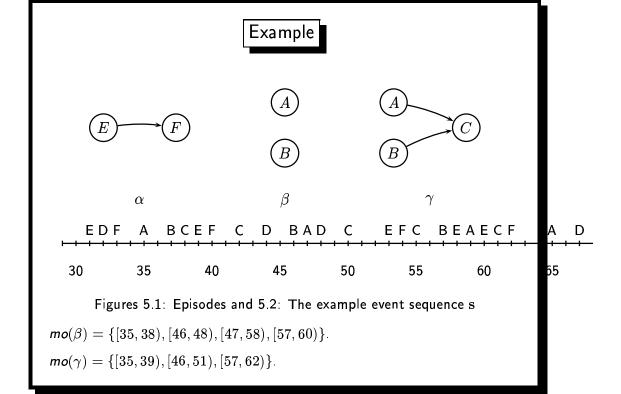

5. Minimal occurrences of episodes

- an alternative approach to discovery of episodes
- no windows
- for each potentially interesting episode, find out the exact occurrences of the episode
- advantages: easy to modify time limits, several time limits for one rule ("if A and B occur within 15 seconds, then C follows within 30 seconds")
- disadvantages: uses lots of space

Data mining, Autumn 2002, Chapter 5: Minimal occurrences of episodes

Definitions

- ullet an episode lpha and an event sequence ${f s}$
- ullet interval $[t_s,t_e)$ is a minimal occurrence of lpha in ${f s}$, if
 - lpha occurs in the window ${f w}=(w,t_s,t_e)$ on ${f s}$
 - α does not occur in any proper subwindow on ${f w}$
- set of (intervals of) minimal occurrences of an episode α : $mo(\alpha) = \{ [t_s, t_e) \mid [t_s, t_e) \text{ is a minimal occurrence of } \alpha \}.$

Data mining, Autumn 2002, Chapter 5: Minimal occurrences of episodes

Episodes rules, new version

- episode rule: $\beta[win_1] \Rightarrow \alpha[win_2]$,
- ullet β and α are episodes such that $\beta \preceq \alpha$
- ullet win $_1$ and win $_2$ are integers
- if episode β has a minimal occurrence at interval $[t_s,t_e)$ with $t_e-t_s \leq \textit{win}_1$, then episode α occurs at interval $[t_s,t'_e)$ for some t'_e such that $t'_e-t_s \leq \textit{win}_2$
- (old version: $\beta[w] \Rightarrow \alpha[w]$, in windows containing β)

- given α and an interval $[u_s,u_e)$, define $occ(\alpha,[u_s,u_e))=$ true if and only if there exists a minimal occurrence $[u_s',u_e')\in mo(\alpha)$ such that $u_s\leq u_s'$ and $u_e'\leq u_e$
- The confidence of an episode rule $\beta \left[\textit{win}_1 \right] \Rightarrow \alpha \left[\textit{win}_2 \right]$ is now

$$\frac{\left|\left\{\left[t_{s},t_{e}\right)\in\mathit{mo}_{\mathit{win}_{1}}(\beta)\bigm|\mathit{occ}(\alpha,\left[t_{s},t_{s}+\mathit{win}_{2}\right)\right)\right\}\right|}{\left|\mathit{mo}_{\mathit{win}_{1}}(\beta)\right|}.$$

Data mining, Autumn 2002, Chapter 5: Minimal occurrences of episodes

Example, cont.

- $\bullet \ \beta \left[3\right] \,\Rightarrow\, \gamma \left[4\right]$
- three minimal occurrences [35,38), [46,48), [57,60) of β of width at most 3 in the denominator
- Only [35,38), has an occurrence of α within width 4, so the confidence is 1/3.
- rule β [3] \Rightarrow γ [5] the confidence is 1.

• temporal relationships can be complex

Data mining, Autumn 2002, Chapter 5: Minimal occurrences of episodes

Frequency and support

- previously: frequency = fraction of windows containing the episode
- no fixed window size
- several minimal occurrences within a window
- ullet support of an episode: the number of minimal occurrences of an episode, |mo(lpha)|

Rule discovery task

- ullet an event sequence ${f s}$
- ullet a frequency threshold min_fr
- ullet a class ${\mathcal E}$ of episodes
- \bullet a set W of time bounds
- ullet find all frequent episode rules of the form $eta\left[\mathit{win}_1\right] \,\Rightarrow\, \alpha\left[\mathit{win}_2\right]$
- $\beta, \alpha \in \mathcal{E}$ and $\textit{win}_1, \textit{win}_2 \in \textit{W}$.

Data mining, Autumn 2002, Chapter 6: Episode discovery process

Chapter 6: Episode discovery process

6. Episode discovery process

- The knowledge discovery process
- KDD process of analyzing alarm sequences
- Discovery and post-processing of large pattern collections
- TASA, Telecommunication Alarm Sequence Analyzer

Data mining, Autumn 2002, Chapter 6: Episode discovery process

The knowledge discovery process

Goal: discovery of useful and interesting knowledge

- 1. Understanding the domain
- 2. Collecting and cleaning data
- 3. Discovery of patterns
- 4. Presentation and analysis of results
- 5. Making onclusions and utilizing results

Pattern discovery is only a part of the KDD process (but the central one)

The knowledge discovery process

Questions implied by the KDD process model:

- How to know what could be interesting?
- How to ensure that correct and reliable discoveries can be made?
- How to discover potentially interesting patterns?
- How to make the results understandable for the user?
- How to use the results?

Data mining, Autumn 2002, Chapter 6: Episode discovery process

Episode discovery process for alarm sequences

Collecting and cleaning the data

- Can take a lot of time
- Collection of alarms rather easy
- Data cleaning? Inaccuracy of clocks
- Missing data?
- What are the event types?
 - Alarm type? Network element? A combination of the two?
- How to deal with background knowledge: network topology, object hierarchies for network elements
- "Alarm predicates": properties of alarms

Discovery of patterns

Strategy:

- 1. Find all potentially interesting patterns
 - \Rightarrow lots of rules
- 2. Allow users to explore the patterns iteratively and interactively
- 1. All potentially interesting patterns
 - Episodes: combination of alarms
 - Association rules: what are alarms like
 - Frequency and confidence thresholds
 - Background knowledge coded into alarm predicates in various alternative ways
 - Network topology used to constrain patterns

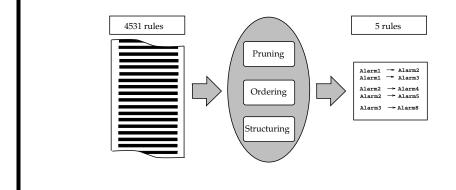

Data mining, Autumn 2002, Chapter 6: Episode discovery process

Presentation and analysis of results

There can be lots of rules

- only a small part is really interesting
- subjective
 - hard to define in advance
 - can depend on the case
- also expected regularities (or their absence) can be of interest
- ⇒ iteration is necessary
- ⇒ support for personal views is needed

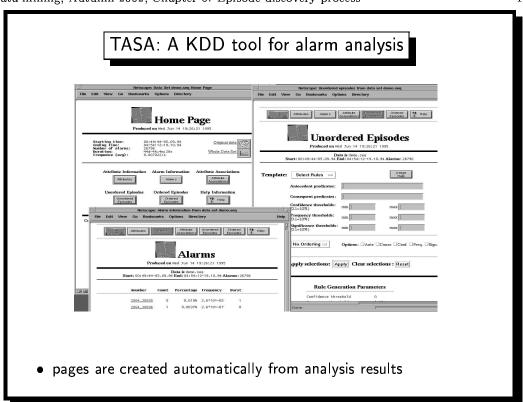

Pruning and ordering:

- alarm predicates on the left or right side
- confidence, frequency, statistical significance

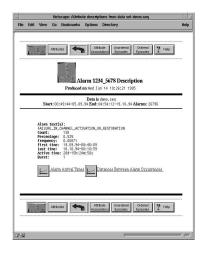

Structuring:

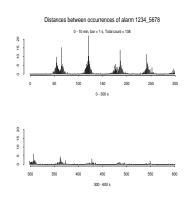

• clusters, hierarchies, etc.

Data mining, Autumn 2002, Chapter 6: Episode discovery process

TASA: Giving an overview of data

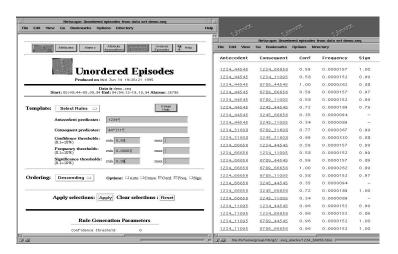

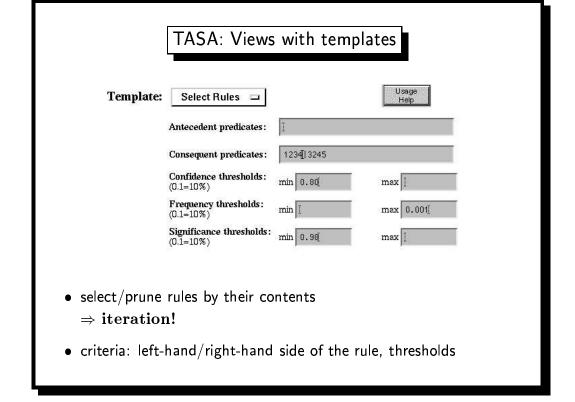

statistical information, histograms

Data mining, Autumn 2002, Chapter 6: Episode discovery process

episode and association rules, views, histograms

Data mining, Autumn 2002, Chapter 7: Generalized framework

8

Chapter 7: Generalized framework

7. Generalized framework

- given a set of patterns, a selection criterion, and a database
- find those patterns that satisfy the criterion in the database
- what has to be required from the patterns
- a general levelwise algorithm
- analysis in Chapter 8

Data mining, Autumn 2002, Chapter 7: Generalized framework

Relational databases

- ullet a relation schema R is a set $\{A_1,\ldots,A_m\}$ of attributes.
- ullet each attribute A_i has a $domain\ Dom(A_i)$
- ullet a *row* over a R is a sequence $\langle a_1,\ldots,a_m
 angle$ such that $a_1\in Dom(A_i)$ for all $i=1,\ldots,m$
- ullet the ith value of t is denoted by $t[A_i]$
- ullet a relation over R is a set of rows over R
- a relational database is a set of relations over a set of relation schema (the database schema)

Discovery task

- ullet ${\cal P}$ is a set of patterns
- $\begin{array}{c} \bullet \ \ q \ \mbox{is a selection criterion, i.e., a predicate} \\ q: \mathcal{P} \times \{ \mathbf{r} \ \middle| \ \mathbf{r} \ \mbox{is a database} \} \rightarrow \{ \mbox{true, false} \}. \end{array}$
- $\bullet \ \varphi$ is selected if $q(\varphi, \mathbf{r})$ is true
- frequent as a synonym for "selected".
- give a database \mathbf{r} , the theory $\mathcal{T}(\mathcal{P}, \mathbf{r}, q)$ of \mathbf{r} with respect to \mathcal{P} and q is $\mathcal{T}(\mathcal{P}, \mathbf{r}, q) = \{ \varphi \in \mathcal{P} \mid q(\varphi, \mathbf{r}) \text{ is true} \}.$

Data mining, Autumn 2002, Chapter 7: Generalized framework

Example

finding all frequent item sets

- ullet a set R a binary database r over R, a frequency threshold min_fr
- $\bullet \ \mathcal{P} = \{X \mid X \subseteq R\},\$
- $\bullet \ q(\varphi,r) = {\rm true} \ {\rm if} \ {\rm and} \ {\rm only} \ {\rm if} \ {\it fr}(\varphi,r) \geq {\it min_fr}$

Selection predicate

- no semantics given for the patterns
- selection criterion takes care of that
- " $q(\varphi, \mathbf{r})$ is true" can mean different things:
- ullet arphi occurs often enough in ${f r}$
- ullet arphi is true or almost true in ${f r}$
- ullet arphi defines, in some way, an interesting property or subgroup of ${f r}$
- ullet determining the theory of ${f r}$ is not tractable for arbitrary sets ${\cal P}$ and predicates q

Data mining, Autumn 2002, Chapter 7: Generalized framework

Methodological point

- find all patterns that are selected by a relatively simple criterion—such as exceeding a frequency threshold—in order to efficiently identify a space of potentially interesting patterns
- other criteria can then be used for further pruning and processing of the patterns
- e.g., association rules or episode rules

Specialization relation

- ullet ${\cal P}$ be a set of patterns, q a selection criterion over ${\cal P}$
- ullet \preceq a partial order on the patterns in ${\cal P}$
- if for all databases ${\bf r}$ and patterns $\varphi, \theta \in \mathcal{P}$ we have that $q(\varphi, {\bf r})$ and $\theta \preceq \varphi$ imply $q(\theta, {\bf r})$,
- ullet then \preceq is a *specialization relation* on ${\mathcal P}$ with respect to q
- $\theta \preceq \varphi$, then φ is said to be *more special* than θ and θ to be *more general* than φ
- $\theta \prec \varphi$: $\theta \preceq \varphi$ and not $\varphi \preceq \theta$
- ullet the set inclusion relation \subseteq is a specialization relation for frequent sets

Data mining, Autumn 2002, Chapter 7: Generalized framework

Generic levelwise algorithm

- the *level* of a pattern φ in \mathcal{P} , denoted $level(\varphi)$, is 1 if there is no θ in \mathcal{P} for which $\theta \prec \varphi$.
- otherwise $\mathit{level}(\varphi)$ is 1+L, where L is the maximum level of patterns θ in $\mathcal P$ for which $\theta \prec \varphi$
- the collection of frequent patterns of level l is denoted by $\mathcal{T}_l(\mathcal{P}, \mathbf{r}, q) = \{ \varphi \in \mathcal{T}(\mathcal{P}, \mathbf{r}, q) \mid \mathit{level}(\varphi) = l \}.$

Algorithm 7.6

Input: A database schema \mathbf{R} , a database \mathbf{r} over \mathbf{R} , a finite set \mathcal{P} of patterns, a computable selection criterion q over \mathcal{P} , and a computable specialization relation \prec on \mathcal{P} .

Output: The set $\mathcal{T}(\mathcal{P}, \mathbf{r}, q)$ of all frequent patterns.

Theorem 7.7 Algorithm 7.6 works correctly.

Examples

- association rules
- episodes: specialization relation
- exact database rules

Data mining, Autumn 2002, Chapter 8: Complexity of finding frequent patterns9

Chapter 8: Complexity of finding frequent patterns

8. Complexity of finding frequent patterns

- border of a theory
- time usage
- guess-and-correct algorithm
- analysis
- borders and hypergraph transversals

Data mining, Autumn 2002, Chapter 8: Complexity of finding frequent patterns

The border of a theory

- ullet $\mathcal{T}(\mathcal{P},\mathbf{r},q)$ of \mathcal{P}
- t whole theory can be specified by giving only the maximally specific patterns in $\mathcal{T}(\mathcal{P},\mathbf{r},q)$
- \bullet collection of maximally specific patterns in $\mathcal{T}(\mathcal{P},\mathbf{r},q)$

Definition

- collection of minimally specific (i.e., maximally general) patterns not in $\mathcal{T}(\mathcal{P}, \mathbf{r}, q)$
- ullet ${\mathcal P}$ be a set of patterns, ${\mathcal S}$ a subset of ${\mathcal P}$, ${\ \, \preceq \ \, }$ a partial order on ${\mathcal P}$
- $\mathcal S$ closed downwards under the relation \preceq : if $\varphi \in \mathcal S$ and $\gamma \preceq \varphi$, then $\gamma \in \mathcal S$
- border $\mathcal{B}d(\mathcal{S})$ of \mathcal{S} consists of those patterns φ such that all more general patterns than φ are in \mathcal{S} and no pattern more specific than φ is in \mathcal{S} :

 $\mathcal{B}d(\mathcal{S}) \ = \ \{\varphi \in \mathcal{P} \mid \text{for all } \gamma \in \mathcal{P} \text{ such that } \gamma \prec \varphi \text{ we have } \gamma \in \mathcal{S},$ and for all $\theta \in \mathcal{P}$ such that $\varphi \prec \theta$ we have $\theta \notin \mathcal{S}\}.$

Data mining, Autumn 2002, Chapter 8: Complexity of finding frequent patterns

139

- positive border $\mathcal{B}d^+(\mathcal{S})$ $\mathcal{B}d^+(\mathcal{S}) = \{ \varphi \in \mathcal{S} \, \big| \, \text{for all } \theta \in \mathcal{P} \, \, \text{such that } \varphi \prec \theta \, \, \text{we have } \theta \notin \mathcal{S} \},$
- ullet the negative border $\mathcal{B}d^-(\mathcal{S})$

 $\mathcal{B}d^-(\mathcal{S})=\{\varphi\in\mathcal{P}\backslash\mathcal{S} \text{for all } \gamma\in\mathcal{P} \text{ such that } \gamma\prec\varphi \text{ we have } \gamma\in\mathcal{S}\}.$

Example

- $R = \{A, \dots, F\}$ $\{\{A\}, \{B\}, \{C\}, \{F\}, \{A, B\}, \{A, C\}, \{A, F\}, \{C, F\}, \{A, C, F\}\}.$
- the negative border is thus

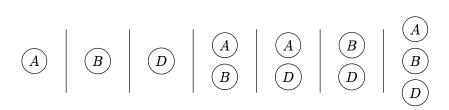

$$\mathcal{B}d^-(\mathcal{F}) = \{\{D\}, \{E\}, \{B, C\}, \{B, F\}\}$$

• the positive border, in turn, contains the maximal frequent sets, i.e.,

$$\mathcal{B}d^{+}(\mathcal{F}) = \{ \{A, B\}, \{A, C, F\} \}$$

ullet frequent episodes in a sequence over events A,\ldots,D

The guess-and-correct algorithm

- levelwise search: safe but sometimes slow
- if there are frequent patterns that are far from the bottom of the specialization relation
- an alternative: start finding $\mathcal{T}(\mathcal{P},\mathbf{r},q)$ from an initial guess $\mathcal{S}\subseteq\mathcal{P}$, and then correcting the guess by looking at the database
- if the initial guess is good, few iterations are needed to correct the result

Data mining, Autumn 2002, Chapter 8: Complexity of finding frequent patterns

Algorithm 8.7

The guess-and-correct algorithm for finding all potentially interesting sentences with an initial guess S.

Input: A database \mathbf{r} , a language \mathcal{P} with specialization relation \leq , a selection predicate q, and an initial guess $\mathcal{S} \subseteq \mathcal{P}$ for $\mathcal{T}(\mathcal{P}, \mathbf{r}, q)$. We assume \mathcal{S} is closed under generalizations.

Output: The set $\mathcal{T}(\mathcal{P}, \mathbf{r}, q)$.

```
Algorithm 8.7
\begin{array}{ll} \mathbf{Method:} \\ 1. & \mathcal{C}^* := \emptyset; \end{array}
             // correct S downward:
            \mathcal{C} := \mathcal{B}d^+(\mathcal{S});
            while \mathcal{C} \neq \emptyset do
                      \mathcal{C}^* := \mathcal{C}^* \cup \mathcal{C};
                      \mathcal{S}:=\mathcal{S}\setminus\{arphi\in\mathcal{C}\;ig|\;q(\mathbf{r},arphi)\;\mathsf{is}\;\mathsf{false}\};
                      \mathcal{C} := \mathcal{B}d^+(\mathcal{S}) \setminus \mathcal{C}^*;
7.
            od;
            // now S \subseteq \mathcal{T}(\mathcal{P}, \mathbf{r}, q); expand S upwards:
            \mathcal{C} := \mathcal{B}d^-(\mathcal{S}) \setminus \mathcal{C}^*;
            while \mathcal{C} \neq \emptyset do
                      \mathcal{C}^* := \mathcal{C}^* \cup \mathcal{C};
10
                      \mathcal{S} := \mathcal{S} \cup \{ arphi \in \mathcal{C} \; \middle| \; q(\mathbf{r}, arphi) \; \mathsf{is true} \};
                      \mathcal{C} := \mathcal{B}d^{-}(\mathcal{S}) \setminus \mathcal{C}^{*};
12.

```

Data mining, Autumn 2002, Chapter 8: Complexity of finding frequent patterns

151

Lemma 8.8 Algorithm 8.7 works correctly.

Theorem 8.9 Algorithm 8.7 uses at most

$$|(\mathcal{S} \triangle \mathcal{T}) \cup \mathcal{B} d(\mathcal{T}) \cup \mathcal{B} d^+(\mathcal{S} \cap \mathcal{T})|$$

evaluations of q, where $\mathcal{T}=\mathcal{T}(\mathcal{P},\mathbf{r},q).$

Initial guesses?

- sampling
- ullet Take a small sample ${f s}$ from ${f r}$
- ullet compute $\mathcal{T}(\mathcal{P},\mathbf{r},q)$ and use it as \mathcal{S}
- Applied to association rules this method produces extremely good results
- with a high probability one can discover the association rules holding in a database using only a single pass through the database
- other method: partitioning the database

Data mining, Autumn 2002, Chapter 8: Complexity of finding frequent patterns

Complexity analysis

Verification problem: assume somebody gives a set $\mathcal{S}\subseteq\mathcal{P}$ and claims that $\mathcal{S}=\mathcal{T}(\mathcal{P},\mathbf{r},q)$. How many evaluations of q are necessary for verifying this claim?

Theorem 8.10 Let \mathcal{P} and $\mathcal{S} \subseteq \mathcal{P}$ be sets of patterns, \mathbf{r} a database, q a selection criterion, and \preceq a specialization relation. If the database \mathbf{r} is accessed only using the predicate q, then determining whether $\mathcal{S} = \mathcal{T}(\mathcal{P}, \mathbf{r}, q)$ (1) requires in the worst case at least $|\mathcal{B}d(\mathcal{S})|$ evaluations of q, and (2) can be done in exactly $|\mathcal{B}d(\mathcal{S})|$ evaluations of q.

Corollary 8.11 Let \mathcal{P} be a set of patterns, \mathbf{r} a database, q a selection criterion, and \leq a specialization relation. Any algorithm that computes $\mathcal{T}(\mathcal{P}, \mathbf{r}, q)$ and accesses the data only with the predicate q must evaluate q on the patterns in $\mathcal{B}d(\mathcal{T}(\mathcal{P}, \mathbf{r}, q))$.

$$R = \{A, \dots, F\}$$

claim: frequent sets are

$$\mathcal{S} = \{\{A\}, \{B\}, \{C\}, \{F\}, \{A,B\}, \{A,C\}, \{A,F\}, \{C,F\}, \{A,C,F\}\}.$$

verify this:

$$\begin{split} \mathcal{B}d^+(\mathcal{S}) &= \{\{A,B\}, \{A,C,F\}\} \text{ and } \\ \mathcal{B}d^-(\mathcal{S}) &= \{\{D\}, \{E\}, \{B,C\}, \{B,F\}\} \end{split}$$

Data mining, Autumn 2002, Chapter 8: Complexity of finding frequent patterns

Computing the border

- ullet ${\cal S}$, we can compute ${\cal B}d^+({\cal S})$ without looking at the data ${f r}$
- ullet the negative border $\mathcal{B}d^-(\mathcal{S})$ is also defined by \mathcal{S}
- \bullet finding the most general patterns in $\mathcal{P} \setminus \mathcal{S}$ can be difficult
- minimal transversals of hypergraphs can be used to determine the negative border
- R be a set; a collection $\mathcal H$ of subsets of R is a simple hypergraph on R, if no element of $\mathcal H$ is empty and if $X,Y\in\mathcal H$ and $X\subseteq Y$ imply X=Y
- ullet elements of ${\cal H}$ are called the *edges*
- ullet elements of R are the *vertices*

ullet a simple hypergraph ${\mathcal H}$ on a set R, a transversal T of ${\mathcal H}$ is a subset of R intersecting all the edges of ${\mathcal H}$

- ullet T is a transversal if and only if $T\cap X
 eq\emptyset$ for all $X\in\mathcal{H}$
- ullet minimal transversal of ${\mathcal H}$ is a transversal T such that no $T'\subset T$ is a transversal
- $\mathcal{T}r(\mathcal{H})$

Data mining, Autumn 2002, Chapter 8: Complexity of finding frequent patterns

Frequent sets

- vertices R; the *complements* of the sets in the positive border be the edges of a simple hypergraph \mathcal{H} .
- for each set X in the positive border we have the set $R \setminus X$ as an edge in \mathcal{H} ;
- $Y \subseteq R$; if there is an edge $R \setminus X$ such that $Y \cap (R \setminus X) = \emptyset$, then $Y \subseteq X$, and Y is frequent.
- ullet if there is no such edge that the intersection is empty, then Y cannot be frequent.
- ullet That is, Y is not frequent if and only if Y is a transversal of \mathcal{H} .
- Minimal transversals are now the minimal non-frequent sets, i.e., the negative border.

Negative border = minimal transversals of the complements of the sets in the positive border

Data mining, Autumn 2002, Chapter 8: Complexity of finding frequent patterns

How to use this?

- what if only the maximal frequent sets are needed, but they are large?
- the levelwise algorithm does not work well
- Dualize-and-advance algorithm:
 - compute some maximal frequent sets using a randomized algorithm
 - compute minimal nonfrequent sets
 - verify them against the database
 - continue until no new sets are found

- 9. Sampling in knowledge discovery
- why sampling?
- what types of knowledge can be discovered using sampling?
- basic techniques of sampling (from files)
- sampling in finding association rules

Why sampling?

- lots of data
- many algorithms are worse that linear
- hunting for relatively common phenomena
- solution: take a sample from the data, and analyze it
- if necessary, confirm the findings by looking at the whole data set

Data mining, Autumn 2002, Chapter 9: Sampling

What types of knowledge?

- estimating the sizes of certain subgroups
- opinion polls: about 1000 persons gives an accuracy of around 2
 % points
- (the size of the population does not have an influence)
- what about very rare phenomena?
- "there exists a subgroup of 100 objects having these and these properties"
- very difficult to verify using sampling, if the population is large

Basic techniques of sampling

- sampling from a file
- given a file of N records t_1, \ldots, tn_n , we wish to choose K from them
- with replacement or without replacement
- with replacement:
 - for i = 1 to K do:
 - st generate a random integer b between 1 and N
 - * output record t_b
 - or sort the generated random integers into order and read the data once

Data mining, Autumn 2002, Chapter 9: Sampling

164

Sampling without replacement, basic method

- ullet keep a bit vector of N bits
- ullet generate random integers b between 1 and N and mark bit b, if it is not already marked
- ullet until K bits have been marked
- read through the bit vector and the data file, and output the selected records

Sampling without replacement, sequential method

```
T:=K;
M:=N;
i:=1;
while T>0 do
let b be a random number from [0,1];
if b < T/M then
output record t_i;
T:=T-1;
M:=M-1;
else
M:=M-1;
end;
end;
```

Data mining, Autumn 2002, Chapter 9: Sampling

Correctness

- ullet by induction on N; for N=0 and N=1, the correctness is clear
- \bullet assume the algorithm works for $N=N^\prime;$ we show that it works for $N=N^\prime+1$
- ullet the first element of the file will be selected with probability K/N, as required
- what about the next elements? two cases: the first element was selected or it wasn't
- probability that an element will be selected is

$$\frac{K}{N}\frac{K-1}{N-1} + \frac{N-K}{N}\frac{K}{N-1} = \frac{K}{N}$$

Sampling for association rules

- Current algorithms require several database passes
- For very large databases, the I/O overhead is significant
- Random sample can give accurate results in sublinear time
- Random samples can be used to boost the discovery of exact association rules (a variant of guess-and-correct algorithm)
- Result: 1 database pass, in the worst case 2 passes

Data mining, Autumn 2002, Chapter 9: Sampling

Simple random sample

Use a random sample only

- Frequent sets can be found in main memory
 very efficient!
- Good news: approximations for frequencies and confidences are good
- Bad news: applications may require exact rules

Algorithm: first pass

Goal: Exact rules in (almost) one pass

- 1. Pick a random sample s from r
- 2. Select a lowered threshold *low_fr < min_fr*
- 3. Compute $\mathcal{S} = \mathcal{F}(s, \textit{low_fr})$ in main memory Goal: $\mathcal{S} \supseteq \mathcal{F}(r, \textit{min_fr})$
- 4. Compute the exact frequencies of sets in ${\mathcal S}$ using the rest of the database

Data mining, Autumn 2002, Chapter 9: Sampling

A quick analysis

- I/O cost: sampling + 1 sequential database pass
- ullet The method may fail (a frequent set is not in ${\cal S}$)
- Larger sample size ⇒ lower failure probability
- Smaller *low_fr* ⇒ lower failure probability
- ullet Smaller $low_fr \Rightarrow \mathcal{S}$ is larger i.e., more sets are checked

How to deal with potential failures?

How much must the threshold be lowered?

How many sets have to be checked?

Negative border

- Recall: the border (both positive and negative) has to be evaluated to verify the result
- \bullet Assume $\mathcal{S} = \mathcal{F}(s, \textit{low_fr})$ has been computed from a sample s
- ullet If any set not in ${\cal S}$ is actually frequent in r, then a set in ${\cal B}d^-({\cal S})$ must be frequent

Data mining, Autumn 2002, Chapter 9: Sampling

Negative border

- After sampling and computing S, verify both S and $Bd^-(S)$ in the rest of the database (and obtain the exact frequencies)
- ullet If no set in $\mathcal{B}d^-(\mathcal{S})$ is frequent, then \mathcal{S} is guaranteed to contain all frequent sets
- ullet If a set X in $\mathcal{B}d^-(\mathcal{S})$ is frequent, then a frequent superset of X might be missed
- \Rightarrow Second pass over the database can be necessary, if there are frequent sets in $\mathcal{B}d^-(\mathcal{S})$

Second pass

- ullet Add the frequent sets in $\mathcal{B}d^-(\mathcal{S})$ to \mathcal{S}
- Repeat:
 - Recompute the negative border of ${\cal S}$
 - Add the new sets in the negative border to ${\cal S}$
- ullet Compute the frequencies of sets in ${\mathcal S}$ in one pass over the database

Data mining, Autumn 2002, Chapter 9: Sampling

Sampling as an instance of guess-and-correct

- ullet Use a random sample to obtain a guess ${\mathcal S}$
 - Goal: $\mathcal{S}\supset\mathcal{F}(r,\textit{min_fr})$
 - 1st pass: correction in one direction only (removal of infrequent sets)
- ullet Negative border $\mathcal{B}d^-(\mathcal{S})$ tells whether frequent sets were missed
 - If necessary, add all possibly frequent sets to $\ensuremath{\mathcal{S}}$
 - Now $\mathcal{S}\supset\mathcal{F}(r,\textit{min_fr})$ is guaranteed
 - 2nd pass: evaluate ${\cal S}$

Dynamic threshold

- ullet Second pass over the database is necessary, if there are frequent sets in $\mathcal{B}d^-(\mathcal{S})$
- ⇒ Frequencies of border sets can be used to estimate the probability of a second pass
- Idea: set the lowered threshold in run time, so that the probability of a second pass is within a desired range

Data mining, Autumn 2002, Chapter 9: Sampling

Chernoff bounds

Theorem 9.8 Given an item set X and a random sample s of size

$$|s| \geq rac{1}{2arepsilon^2} \ln rac{2}{\delta}$$

the probability that $|\mathit{fr}(X,s) - \mathit{fr}(X)| > \varepsilon$ is at most δ .

Proof The Chernoff bounds give the result

 $Pr[|x-np|>a]<2e^{-2a^2/n}$, where x is a random variable with binomial distribution B(n,p). For the probability at hand we thus have

$$\begin{split} ⪻[|\mathit{fr}(X,s)-\mathit{fr}(X)|>\varepsilon]\\ = ⪻[|\mathit{fr}(X,s)-\mathit{fr}(X)|\cdot|s|>\varepsilon\,|s|]\\ \leq &2e^{-2(\varepsilon\,|s|)^2/|s|}\leq \delta. \end{split}$$

What does this mean?

Sufficient sample sizes (note: Chernoff bounds are rough!)

ε	δ	Sample size
0.01	0.01	27 000
0.01	0.001	38 000
0.01	0.0001	50 000
0.001	0.01	2 700 000
0.001	0.001	3 800 000
0.001	0.0001	5 000 000

Table 9.1 Sufficient sample sizes, given ε and δ .

Data mining, Autumn 2002, Chapter 9: Sampling

What about several sets?

 ${f Corollary}$ 9.9 Given a collection ${\cal S}$ of sets and a random sample s of size

$$|s| \geq rac{1}{2arepsilon^2} \ln rac{2|\mathcal{S}|}{\Delta},$$

the probability that there is a set $X\in\mathcal{S}$ such that $|\mathit{fr}(X,s)-\mathit{fr}(X)|>\varepsilon$ is at most $\Delta.$

Proof By Theorem 9.8, the probability that $|\mathit{fr}(X,s) - \mathit{fr}(X)| > \varepsilon$ for a given set X is at most $\frac{\Delta}{|\mathcal{S}|}$. Since there are $|\mathcal{S}|$ such sets, the probability in question is at most Δ .

Experiments

- Three benchmark data sets from [AS94]
- Assumption: real data sets can be much larger
- Sampling with replacement (analysis is easier)
- Sample sizes from 20,000 to 80,000
- Every experiment was repeated 100 times
- *low_fr* was set so that the probability of missing any given frequent set is at most 0.001

Data mining, Autumn 2002, Chapter 9: Sampling

Table 9.5 Number of itemsets considered for data set T10.I4.D100K

Exact I/O savings?

- Depends on storage structures and sampling methods
- Example 1:

Database size 10 million rows, sample size 20 thousand rows, 100 rows/disk block

- \Rightarrow sampling reads at most 20 % of the database
- Example 2:

database size 10 billion rows

 \Rightarrow sampling reads at most 0.02 % of the database
