Motivational Example

- New possible laptop for CS dept use
  - Lenovo 400, dual-core, Intel Centrino 2 technology
  - Ubuntu Linux 8.10
- Wakeup from suspend/hibernation, freezes often
- Read, study, experiment – some 15 hours?
  - No network?, at home/work?, various units?, …, ???
  - Problem with Gnome desktop, not with KDE, …, ???
- Could two processors cause it?
  - Shut down one processor during hibernation/wakeup
  - Wakeup works fine now
- Same problem with many new laptops running Linux
  - All new laptops with Intel Centrino 2 with same Linux driver?
- Concurrency problem in display driver startup?
  - Bug not found yet, use 1-cpu work-around

[http://git.kernel.org/?p=linux/kernel/git/torvalds/linux-2.6.git;a=commitdiff;h=70740d6c93030b339b4ad17fd58ee135dfc13913](http://git.kernel.org/?p=linux/kernel/git/torvalds/linux-2.6.git;a=commitdiff;h=70740d6c93030b339b4ad17fd58ee135dfc13913) (search "i915_enable_vblank" … )
Deadlock: Background

Basic problem: a process needs multiple objects at the same time

Mutex: competition for one object (critical section)
Deadlock: an Example

P
reserve A? OK.
reserve B? Wait
(for resource held by Q)

Q
reserve B? OK.
reserve A? Wait
(for resource held by P)
Deadlock cycle in resource reservation graph
Does this graph contain a deadlock?
Resource Reservation Graph

Does this graph contain a deadlock?
Gridlock

Processes: cars 1, 2, 3 and 4
Resources: quadrants a, b, c, d
  – Car 4 needs quadrants d and a (exclusive use for each)

Real life gridlock: http://img209.imageshack.us/img209/5781/deadlocknajkcomafarialibh3.jpg

(Fig. 6.1 [Stal06])
Consequences

• The processes do not advance
  – Cars do not move

• Resources remain reserved
  – Cpu? Street quadrant?
  – Memory? I/O-devices?
  – Logical resources (semaphores, critical sections, ...)?

• The computation fails
  – Execution never finishes?
    • One application?
  – The system crashes? Traffic flow becomes zero?
Resources

- **Reusable resources**
  - Limited number or amount
  - Wait for it, allocate it, deallocate (free) it
  - Memory, buffer space, intersection quadrant
  - Critical section code segment execution
  - ...

- **Consumable resources**
  - Unlimited number or amount
  - Created and consumed
  - Someone may create it, wait for it, destroy it
  - Message, interrupt, turn for critical section
  - ...

13.11.2009 Copyright Teemu Kerola 2009
1: scenario Q alone

Q requests B when P has A&B

Q gets B when P has A

P alone

11.11.2009 Copyright Teemu Kerola 2009
Q gets B when P has A, P release A, Q gets A, Q release B, A gets B, A release B
Definitions

- **Deadlock**
  - Eternal wait in blocked state
  - Does not block processor (unless one resource is processor)

- **Livelock**
  - Two or more processes continuously change their state (execute/wait) as response to the other process(es), but never advance to real work
  - E.g., ping-pong ”you first – no, you first - ...”
    - two processes alternate offering the turn to each other - no useful work is started
  - Consumes processor time

- **Starvation**
  - the process will never get its turn
  - E.g., in ready-to-run queue, but never scheduled
Deadlock Problems

• How to know if deadlock exists?
  – How to locate deadlocked processes?
• How to prevent deadlocks?
• How to know if deadlock might occur?
• How to break deadlocks?
  – Without too much damage?
  – Automatically?
• How to prove that your solution is free of deadlocks?
Good Deadlock Solution

- Prevents deadlocks in advance, or detects them, breaks them, and fixes the system
- Small overhead
- Smallest possible waiting times
- Does not slow down computations when no danger exists
- Does not block unnecessarily any process when the resource wanted is available
Conditions for Deadlock

- **Three policy conditions**
  - S1. **Mutual exclusion**
    - one user of any resource at a time (not just code)
  - S2. **Hold and wait**
    - a process may hold allocated resources while waiting for others
  - S3. **No preemption**
    - resource can not be forcibly removed from a process holding it

- **A dynamic (execution time) condition takes place**
  - D1. **Circular wait**: a closed chain of processes exists, each process holds at least one resource needed by the next process in chain

E.G. Coffman, 1971

Dining Philosophers (Dijkstra)

Philosopher:
think
take two forks ... ... one from each side
eat rice until satisfied
return the forks

Problem:
how to reserve the forks without causing
- deadlock
- starvation
and everybody may be present

See philosopher art in web

Dining Philosophers in Java

- Tapio Lehtomäki, MikroBitti
- Load program from course schedule page
- Modify paths in script philosophers.bat and run it
- Modify program for homework?
  - Next year?
Possible deadlock – not good
  – All 5 grab left fork “at the same time”

```c
/* program  diningphilosophers */
semaphore fork [5] = {1}; /* mutex, one at a time */
int i;
void philosopher (int i)
{
    while (true)
    {
        think();
        wait (fork[i]); /* left fork */
        wait (fork [((i+1) mod 5)]); /* right fork */
        eat();
        signal(fork [((i+1) mod 5)]);
        signal(fork[i]);
    }
}
void main()
{
    parbegin (philosopher (0), philosopher (1), philosopher (2),
              philosopher (3), philosopher (4));
}
```
/* program diningphilosophers */
semaphore fork[5] = {1};
semaphore room = {4}; /* only 4 at a time, 5th waits */
int i;
void philosopher (int I)
{
    while (true)
    {
        think();
        wait (room);
        wait (fork[i]);
        wait (fork [(i+1) mod 5]);
        eat();
        signal (fork [(i+1) mod 5]);
        signal (fork[i]);
        signal (room);
    }
}
void main()
{
    parbegin (philosopher (0), philosopher (1), philosopher (2),
              philosopher (3), philosopher (4));
}

- No deadlock, no starvation, and no company while eating – not good
- Waiting when resources are available – not good

which scenario?
Deadlock Prevention

- How to prevent deadlock occurrence in advance?
- Deadlock possible only when all 4 conditions are met:
  - S1. Mutual exclusion
  - S2. Hold and wait
  - S3. No preemption
  - D1. Circular wait

Solution: disallow **any one** of the conditions
- S1, S2, S3, or D1?
- Which is possible to disallow?
- Which is easiest to disallow?
Disallow S1 (mutual exclusion)

- Can not do always
  - There are reasons for mutual exclusion!
    - Can not split philosophers fork into 2 resources
- Can do sometimes
  - Too high granularity blocks too much
    - Resource *room* in trivial solution #2
  - Finer granularity allows parallelism
    - Smaller areas, parallel usage, more locks
    - More administration to manage more locks
    - Too fine granularity may cause too much administration work
  - Normal design approach in data bases, for example
- Get more resources, avoid mutex competition?
  - Buy another fork for each philosopher?
Disallow S2 (hold and wait)

- Request all needed resources at one time
- Wait until all can be granted simultaneously
  - Can lead to starvation
- Reserve both forks at once (simultaneous wait!)
- Neighbouring philosophers eat all the time alternating

- Inefficient
  - long wait for resources (to be used much later?)
  - worst case reservation (long wait period for resources which are possibly needed - who knows?)
- Difficult/impossible to implement?
  - advance knowledge: resources of all possible execution paths of all related modules ...

13.11.2009
Copyright Teemu Kerola 2009
Disallow S3 (no preemption)

- Allow preemption in crisis
- Release of resources ⇒ fallback to some earlier state
  - Initial reservation of these resources
  - Fall back to specific checkpoint
  - Checkpoint must have been saved earlier
  - Must know when to fall back!

- OK, if the system has been designed for this
  - Practical, if saving the state is cheap and the chance of deadlock is to be considered
  - Standard procedure for transaction processing

```c
wait (fork[i]);
if "all forks taken" then
    "remove fork" from philosopher [i⊕1]
wait (fork[i⊕1])
```

- What will philosopher i⊕1 do now? Think? Eat? Die?
Disallow D1 (circular wait)

- Linear ordering of resources
  - Make reservations in this order only – no loops!
- Pessimistic approach – prevent “loops” in advance
  - Advance knowledge of resource requirements needed
  - Reserve all at once in given order
  - Prepare for ”worst case” behavior

<table>
<thead>
<tr>
<th>Forks in global ascending order philosophers 0, 1, 2, 3:</th>
</tr>
</thead>
<tbody>
<tr>
<td>wait (fork[i]);</td>
</tr>
<tr>
<td>wait (fork[i+1]);</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>last philosopher 4:</td>
</tr>
<tr>
<td>wait (fork[0]);</td>
</tr>
<tr>
<td>wait (fork[4]);</td>
</tr>
</tbody>
</table>

- Optimistic approach – worry only at the last moment
  - Reservation dynamically as needed (but in order)
  - Reservation conflict => restart from some earlier stage
  - Must have earlier state saved somewhere
Deadlock Detection and Recovery

- Let the system run until deadlock problem occurs
  - “Detect deadlock existence”
  - “Locate deadlock and fix the system”
- Detection is not trivial:
  - Blocked group of processes is deadlocked? or
  - Blocked group is just waiting for an external event?
- Recovery
  - Detection is first needed
  - Fallback to a previous state (does it exist?)
  - **Killing** one or more members of the deadlocked group
    - Must be able to do it **without overall system damage**
- Needed: information about resource allocation
  - In a form suitable for deadlock detection!

13.11.2009
Copyright Teemu Kerola 2009
Resource Allocation

- Processes \( P_i \in P_1..P_n \)
- Resources (or objects) \( R_j \in R_1..R_m \)
- Number of resources of type \( R_j \)
  - total amount of resources \( R = (r_1, \ldots, r_m) \)
  - currently free resources \( V = (v_1, \ldots, v_m) \)
- Allocated resources (allocation matrix)
  - \( A = [a_{ij}] \), “process \( P_i \) has \( a_{ij} \) units of resource \( R_j \)”
- Outstanding requests (request matrix)
  - \( Q = [q_{ij}] \), “process \( P_i \) requests \( q_{ij} \) units of resource \( R_j \)”
How many R4 resources **exists**?  

Which resources are **now** free?  

P2 has **now** R1 and R2, P2 wants **now** R3 and R5  

Who has **now** R4?  

Is there **now** a deadlock or not?  

(Fig. 6.10 [Stal06])
Deadlock Detection (Dijkstra) (4)

1. Find a (any) process that could terminate
   - All of its current resource requests can be satisfied

2. Assume now that
   a. This process terminates, and
   b. It releases all of its resources

3. Repeat 1&2 until can not find any more such processes

4. If any processes still exist, they are deadlocked
   a. They all each need something
   b. The process holding that something is waiting for something else
      - That process can not advance and release it
Deadlock Detection Algorithm (DDA)

DL1. [Remove the processes with no resources]
Mark all processes with null rows in \( A \).

DL2. [Initialize counters for available objects]
Initialize a working vector \( W = V \).

DL3. [Search for a process \( P_i \) which could get all resources it requires]
Search for an unmarked row \( i \) such that
\[
q_{ij} \leq w_j \quad j = 1..n
\]
If none is found terminate the algorithm.

DL4. [Increase \( W \) with the resources of the chosen process]
Set \( W = W + A_{ir} \) i.e. \( w_j = w_j + a_{ij} \) when \( j = 1..n \)
Mark process \( P_i \) and return to step DL3.

When the algorithm terminates, unmarked processes correspond to deadlocked processes. Why?
Example: Initial state

Example: Breaking Deadlocks

- Processes P1 and P2 are in deadlock  
  - What next?
- Abort P1 and P2  
  - Most common solution
- Rollback P1 and P2 to previous safe state, and try again  
  - Rollback states **must exist**  
  - May deadlock again (or may not!)
- Abort P1 because it is less important  
  - Must have some basis for selection  
  - Who makes the decision? Automatic?
- Preempt R3 from P1  
  - Must be **able** to preempt (easy if R3 is CPU?)  
  - Must know **what** to preempt from **whom**  
  - **How many** resources need preemption?
Deadlock Avoidance with DDA

- Use Dijkstra’s algorithm to avoid deadlocks in advance?
- Banker’s Algorithm
  - Originally for one resource (money)
  - Why ”Banker’s”?
    - ”Ensure that a bank never allocates its available cash so that it can no longer satisfy the needs of all its customers”
Banker’s Algorithm (6)

- Keep state information on resources allocated to each process
- Keep state information on number of resources each process might still allocate
- For each resource allocation, first find an ordering which allows processes to terminate, if that allocation is made
  - Assume that allocation is made and then use DDA to find out if the system remains in a safe state even in the worst case
  - If deadlock is possible, reject resource request
  - If deadlock is not possible, grant resource request
Deadlock Avoidance with Banker’s Algorithm

Matrices as before, and some more

- For each process: the maximum needs of resources
  - \( C = [c_{ij}] \), “Pi may request \( c_{ij} \) units of Rj”

- The current hypothesis of resources in use
  - \( A' = [a'_{ij}] \), “if this allocation is made, Pi would have \( a'_{ij} \) units of Rj”

- The current hypothesis of future maximum demands
  - \( Q' = [q'_{ij}] \), “Pi could still request \( q'_{ij} \) units of Rj”

  \( Q' = C - A' \)

- Apply DDA to \( A' \) and \( Q' \)
  - If no deadlock possible, grant resource request
Banker’s Algorithm Example

DDA: no deadlock, allocation request OK
Avoidance: Problems

- Each allocation: a considerable overhead
  - Run Banker’s algorithm for 20 processes and 100 resources?
- Knowledge of maximum needs
  - In advance?
    - An educated guess? Worst case?
  - Dynamically?
    - Even more overhead
- A safe allocation does not always exist
  - An unsafe state does not always lead to deadlock
  - You may want to take a risk!

Another Banker’s Algorithm example: B. Gray, Univ. of Idaho
http://www.if.uidaho.edu/~bgray/classes/cs341/doc/banker.html
Summary

- **Difficult real problem**
- **Can detect deadlocks**
  - Need specific data on resource usage
- **Difficult to break deadlocks**
  - How will killing processes affect the system?
- **Can prevent deadlocks**
  - Prevent any one of those four conditions
    - E.g., reserve resources always in given order
  - Can analyze system at resource reservation time to see whether deadlock might result
    - Complex and expensive
