1

## Order Processing Example

- Create model, Fig 9.1
- How to get parameter values?
  - OS
  - TP monitor
  - DBMS
  - Application

Customers	disk A
Inventory	disk A?
Orders	disk B
Paging	disk C

Job classes:   Order entry   init R=3.1 sec  
                    Order query

16.4.2002

2

## Measurement Process

- See Fig. 9.2
- Which data is needed?
- Where to place instrumentation?
- When to collect data?
- How long to collect data?
- How to account for measurement error?
  - load caused by the instrumentation?
  - does instrumentation have side effects?

16.4.2002

Copyright Teemu Kerola 2002

3

## HW Monitors

- Collect raw data
- Wire monitors to physical units

Fig. 2.7 & Tbl 2.3 [Ferrari 78]

- HW tool characteristics (1978)

Tbl. 2.2 [Ferrari 78]

- Can be made to work with no (or very little) side effects or load
  - why?

16.4.2002

Copyright Teemu Kerola 2002

4

## SW Monitors

- Modify SW to collect data  
Application? OS? DBMS?
- Use off-the-shelf monitoring system  
OS? DBMS? Other?
- Problem: runs in the same system that is being monitored
  - biased data. uses system resources
- Compare to HW monitors

Tbl 7.1 [Jain 91]

16.4.2002

Copyright Teemu Kerola 2002

5

## Use Accounting Data for Parameter Estimation

- Good: it is there already (or is it?)
- Bad: it is built for accounting purposes
- Who used resources?
  - user id, program, project, account nr or class
- What resources were used?
  - CPU time, I/O op counts, NW use, mem use
- When were resources used?
  - user time only?
  - Granularity may be too coarse?

16.4.2002

Copyright Teemu Kerola 2002

6

## Program Analyzers

- Runs with some programs
  - Designed for one program
- IBM DB2, IMS, CICS
- Generic analyzers
    - gprof
    - get nr. of transactions, CPU time, mpl

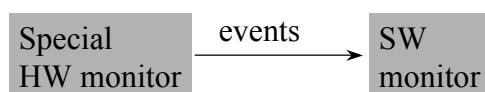

16.4.2002

Copyright Teemu Kerola 2002

7

## Hybrid Monitors

- HW + SW

- Data filtering
  - Post run analysis
  - Can be very large monitoring system
    - as large as actual monitored system
- |                                   |                      |
|-----------------------------------|----------------------|
| same system?<br>different system? | [Wybraniets & Haban] |
|-----------------------------------|----------------------|

16.4.2002

8

## Events or Sampling

- Event driven or time driven data gathering?
- Volume?
- Data collection method?
- Data storage? Where?
- Overhead?

16.4.2002

Copyright Teemu Kerola 2002

9

## Events

- Predefined system events
  - “I/O request completed”
  - “process terminates”
- Create events
  - how much overhead?
- Log them into log files, or
- Send them to filtering and analysis

16.4.2002

Copyright Teemu Kerola 2002

10

## Sampling

- Good: smaller volume
- Bad: may miss something
- Sampling rate? too high? too low?
- Collect state information
  - “CPU busy”, “disk busy”
  - “amount of memory at use”
- Assign data to threads/processes/programs?
  - “CPU busy 5 ms due to process P” ???

16.4.2002

Copyright Teemu Kerola 2002

11

## Measurement Unit

- Module
- Subroutine
- Statement
  - language dependent?
- Machine instruction?

16.4.2002

Copyright Teemu Kerola 2002

12

## Time Unit

- Real time?
- System time?
- External time?
- CPU time?
- Elapsed time?

16.4.2002

Copyright Teemu Kerola 2002

13

## Instrumentation

- When?
  - source code
  - compiler generated code
  - before linking, or at load time
  - run time
- How?
  - source code? Obj. code?
  - run time env.? OS? HW?

16.4.2002

Copyright Teemu Kerola 2002

14

# Report

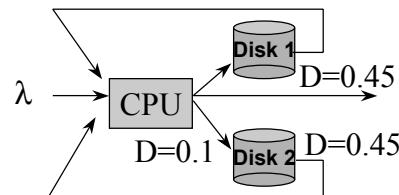

- Hierarchical
- Graphics
- What time is used?
  - inherited time
  - own time

16.4.2002

Copyright Teemu Kerola 2002

15

## Parameter Values

- Job classes
  - clustering? factor analysis?
- $N_r \lambda_r Z_r M_r$ 
  - external to system: plain measurements
- $D_{ir}$ 
  - internal: need internal data - e.g.,  $U_{ir}$
  - $D_{ir} = U_{ir} * T / C_{0r}$
  - sometimes get only  $U_i$

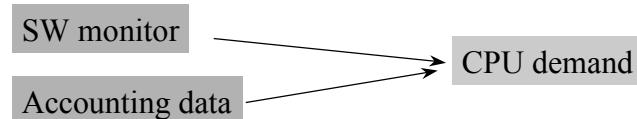

16.4.2002

Copyright Teemu Kerola 2002

16

## Parameter Example

Fig. 9.3 [Men 94]

16.4.2002

17

## Transaction Processing System Data

- Have  $U_{\text{total}} = U_{\text{cpu, OS}} + U_{\text{cpu,TP}} + U_{\text{cpu,prog}}$
- Need  $U_{\text{cpu,r}}$  for each transaction class r

$$U_{\text{cpu,r}} = U_{\text{cpu}} * f_{\text{cpu,tp}} * f_{\text{tp,r}}$$

$$\frac{U_{\text{CPU,TP}}}{\sum_s U_{\text{CPU,s}}} \quad \frac{T_{\text{CPU,r}}^{\text{TP}}}{\sum_{s \in \text{TP}} T_{\text{CPU,s}}^{\text{TP}}}$$

↑                              ↑

sampling system monitor      analyzer for TP monitor

16.4.2002

Copyright Teemu Kerola 2002

18

## TP Example (1)

- System with 3 classes:
  - Batch (B), Interactive (I)
  - TP (queries & updates)
- System monitor:  $T=1800$ ,  $U_{cpu}^{total} = 72\%$
- Accounting:  $U_{cpu,B}^{noOS} = 32\%$     $U_{cpu,I}^{noOS} = 10\%$     $U_{cpu,TP}^{noOS} = 28\%$
- TP analyzer:
  - 1200 queries in 120 sec
  - 400 updates in 140 sec

0.35 sec per update
- Now,
 
$$U_{cpu,U} = 0.72 * \frac{28}{70} * \frac{140}{260} = 15.5\%$$

$$D_{cpu,U} = U_{cpu,U} X_{0,U} = 15.5\% * \frac{1800}{400} = 0.70sec$$

$$D_{cpu,Q} = \left[ 0.72 * \frac{28}{70} * \frac{140}{260} \right] * \frac{1800}{1200} = 0.20sec$$

16.4.2002

Copyright Teemu Kerola 2002

19

## Arrival Rate & MPL

- Assume flow balance
  - arrival count  $\cong$  completion count
  - $\lambda_r = C_{0r} / T$
- Average mpl:
 
$$\bar{N} = \lambda R = \frac{1}{T/n} * \frac{\sum e_i}{n} = \frac{\sum e_i}{T}$$

elapsed time for job i  
nr of jobs

Fig 9.4 [Men 94]

16.4.2002

Copyright Teemu Kerola 2002

20

## M and Z (2)

- M - Number of terminals

session length  
(from accounting logs)

$$\overline{M} = \text{"session rate"} * \text{"session time"} = \frac{n}{T} * \frac{\sum S_i}{n} = \frac{\sum S_i}{T}$$

- Z:

$$Z = \frac{M}{X} - R = \frac{M}{C_0 / T} - R$$

average measured  
elapsed time  
in system

Example: T = 1 hour = 3600 sec

M=40 4900 interactive commands

2.5 sec aver resp time

$$Z = 40 / (4900/3600) - 2.5 = 29.4 - 2.5 = 26.9 \text{ sec.}$$

## CPU Demand: D<sub>cpu,r</sub>

$$D_{cpu,r} = U_{cpu,r} * \frac{T}{C_{0,r}} = U_{cpu}^{Total} * f_{cpu,r} * \frac{T}{C_{0,r}}$$

$$\text{where } f_{cpu,r} = \frac{C_{0,r}}{\sum_s C_{0,s}} = f(jobs)$$

$$\text{or } f_{cpu,r} = \frac{U_{cpu,r}^{mon}}{\sum_s U_{cpu,s}^{mon}} = f(time)$$

$$\text{or } f_{cpu,r} = \frac{nrIO(r)}{\sum_s nrIO(s)} = f(nr IO's)$$

or ...

## Capture Ratio <sub>(1)</sub>

- Capture ratio
  - class dependent!
- Example:

$$\begin{aligned}
 C_{batch} &= 0.80 & C_{term} &= 0.60 \\
 T &= 7200 \text{ sec} & U_{cpu}^{Total} &= 64\% \\
 T_{cpu,batch}^{Meas} &= T_{cpu,term}^{Meas} = 1500 \text{ sec} \\
 T_{cpu,batch} &= \frac{1500}{0.80} = 1875 \text{ sec (actual!)} \\
 T_{cpu,term} &= \frac{1500}{0.60} = 2500 \text{ sec} & T_{cpu} &= 4375 \text{ sec} \\
 U_{cpu,batch} &= U_{cpu}^{Total} * f_{cpu,batch} = 0.64 * \frac{1875}{4375} = 0.27
 \end{aligned}$$

actual,  
not measured

measure  
estimate  
calibrate  
quess

Copyright Teemu Kerola 2002

23

## D<sub>ir</sub> for Disks

IO count → Mean service time

$$U_i^{Total} = \frac{IOC_i * MST_i}{T} \text{ (or from HW monitor)}$$

$$D_{ir} = \frac{U_i^{Total} * T}{C_{0,r}} * f_{ir} = \frac{IOC_i * MST_i}{C_{0,r}} * f_{ir}$$

where  $f_{ir} = \frac{IOC_{ir}}{IOC_{0,r}}$  (user data)

or  $f_{ir} = \frac{SWAPC_{ir}}{SWAPC_{0,r}}$  (swap data)

or  $f_{ir} = \frac{PageInC_{ir}}{PageInC_{0,r}}$  (paging data)

16.4.2002

Copyright Teemu Kerola 2002

24

## Delay Node

- High disk utilization: include all disks in model
- Low (< 5%?) disk utilization: may use one aggregate **delay** node in model
  - no queueing likely ....

$$D_{ir} = \sum_{disks\ j} \frac{U_j^{Total} * T}{C_{0,r}} * f_{jr} = \frac{T}{C_{0,r}} \sum_{disks\ j} U_j^{Total} * f_{jr}$$

16.4.2002

Copyright Teemu Kerola 2002

25

## Order Processing Example

Tbl 9.1 [Men 94]
------------------

- Want: Arrival rates, demands
- CPU demands
- File ops per application class
- File ops per disk
- Disk util. & demands per class
- $Z_r$ 's when  $R_r$ 's are known: use Little's Law

Tbl 9.3
---------

Tbl 9.4
---------

Tbl 9.5
---------

Tbl 9.6
---------

16.4.2002

Copyright Teemu Kerola 2002

26

## Estimate $Z_r$ 's if $R_r$ unknown

- Use subsystem as open model
- Use  $\lambda_r = X_{0r}$
- Solve model, get  $R_r = (3.00, 0.98, 2.23)$
- Use those estimates to compute

$$Z_r = M_r / X_{0r} - R_r$$

$$Z_{OE} = 10/1.43 - 3.0 = 3.99 \text{ (vs 3.75)}$$

$$Z_{OI} = 5/0.83 - 0.98 = 5.04 \text{ (vs 5.04)}$$

$$Z_{Ot} = 5/0.31 - 2.23 = 13.9 \text{ (vs. 13.9)}$$

16.4.2002

Copyright Teemu Kerola 2002

27

## Calibration

- Use parameters to build baseline model
- Use solver
  - e.g., PMVA fig.9.1.out
  - get  $R_{OE} = 2.5$  (not 3.25 as in Tbl 9.1)
- What now? Calibrate model!
  - scale (or add to) output to match data
  - adjust MPL or its distribution
  - add new class fig.9.1a.out
  - modify demands (at bottleneck) fig.9.1b.out
  - add ghost server for unaccounted for load
