Ch 4 Synchronization

Clocks and time
Global state
Mutual exclusion
Election algorithms
Distributed transactions

Tanenbaum, van Steen: Ch 5
CoDoKi: Ch 10-12 (3rd ed.)

Skew between computer clocks in a distributed system

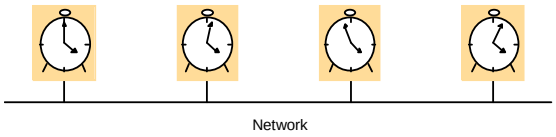

Figure 10.1

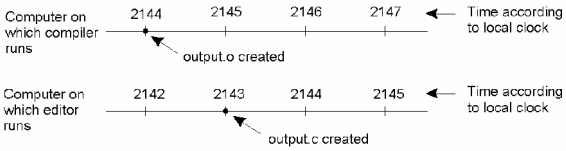
Clock Synchronization



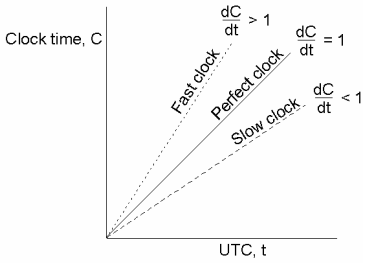
When each machine has its own clock, an event that occurred after another event may nevertheless be assigned an earlier time.

Time and Clocks

Needs	Clocks
real time	universal time (network time)
interval length	computer clock
order of events	network time (universal time)

NOTICE: ***time*** is ***monotonous***

Clock Synchronization Problem



drift rate: 10^{-6}

1 ms ~ 17 min

1 s ~ 11.6 days

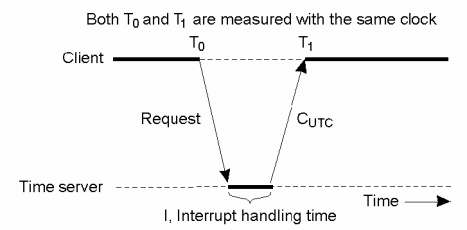
UTC: coordinated universal time
accuracy:
radio 0.1 – 10 ms,
GPS 1 us

The relation between clock time and UTC when clocks tick at different rates.

Synchronization of Clocks: Software-Based Solutions

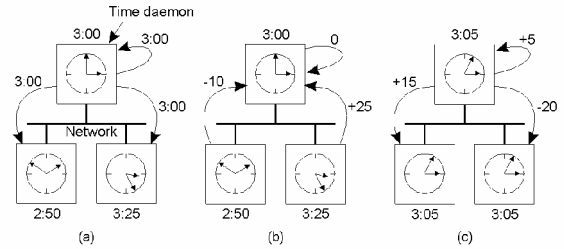
- Techniques:
  - time stamps of real-time clocks
  - message passing
  - round-trip time (local measurement)
- Cristian's algorithm
- Berkeley algorithm
- Network time protocol (Internet)

Cristian's Algorithm



Current time from a time server: UTC from radio/satellite etc
Problems:
- time must never run backward
- variable delays in message passing / delivery

The Berkeley Algorithm



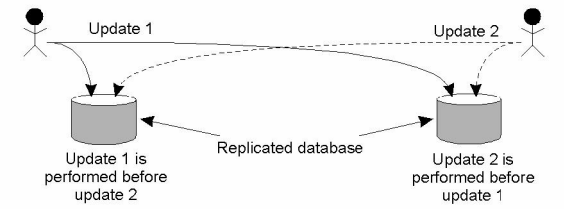
a) The **time daemon asks** all the other machines for their clock values
b) The machines answer
c) The time daemon tells everyone how to adjust their clock *(be careful with averages!)*

Clocks and Synchronization

Needs
- "*causality*": real-time order ~ timestamp order ("behavioral correctness" – seen by the user)
- *groups* / *replicates*: all members see the events in the same order
- "*multiple-copy-updates*": order of updates, consistency conflicts?
- *serializability of transactions*: bases on a common understanding of transaction order

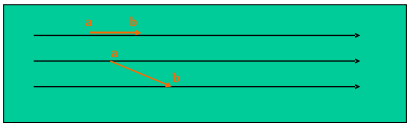
A physical clock is **not always** sufficent!

Example: Totally-Ordered Multicasting (1)



Updating a replicated database and leaving it in an inconsistent state.

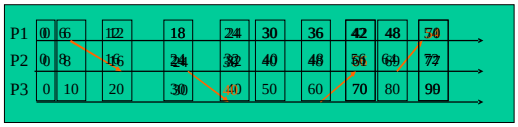
Happened-Before Relation "a -> b"



- if a, b are *events in the same process*, and a occurs before b, then a -> b
- if a is the event of a *message being sent*, and b is the event of the *message being received*, then a -> b
- a || c if neither a -> b nor b -> a (a and b are *concurrent*)

Notice: if a -> b and b -> c then a -> c

Logical Clocks: Lamport Timestamps



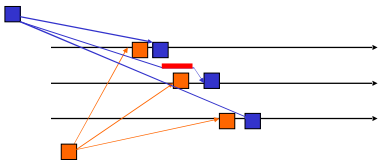
process p_i , event e , clock L_i , timestamp $L_i(e)$
- ***at p_i*** : before each event $L_i = L_i + 1$
- when p_i sends a ***message*** m to p_j
  1. p_i: ($L_i = L_i + 1$); $t = L_i$; message = (m, t) ;
  2. p_j: $L_j = \max(L_j, t)$; $L_j = L_j + 1$;
  3. L_j(receive event) = L_j ;

Lamport Clocks: Problems

1. Timestamps do not specify the order of events
   - e -> e' => L(e) < L(e')

   BUT
   - L(e) < L(e') does not implicate that e -> e'
2. Total ordering
   - problem: define order of e, e' when L(e) = L(e')
   - solution: extended timestamp (T_i, i), where T_i is $L_i(e)$
   - definition: (T_i, i) < (T_j, j) if and only if either $T_i < T_j$ or $T_i = T_j$ and i < j

Example: Totally-Ordered Multicasting (2)



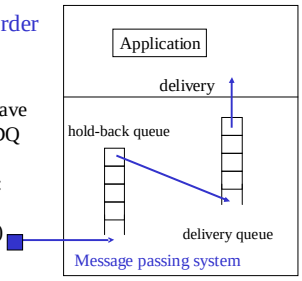
Total ordering:
all receivers (applications) see all messages in the same order (which is not necessarily the original sending order)

Example: multicast operations, group-update operations

Example: Totally-Ordered Multicasting (3)

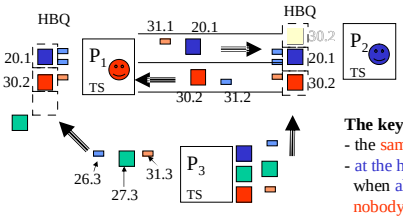
Guaranteed delivery order

- *new* message => HBQ
- when *all predecessors* have arrived: message => DQ
- when *at the head of DQ*: message => application (application: *receive* …)



Algorithms:
see. Defago et al ACM CS, Dec. 2004

Example: Totally-Ordered Multicasting (4)



Original timestamps
P_1 19
P_2 29
P_3 25

The key idea
- the same order in all queues
- at the head of HBQ: when all ack's have arrived nobody can pass you

Multicast:
- everybody receives the message (incl. the sender!)
- messages from one sender are received in the sending order
- no messages are lost

Various Orderings

- Total ordering
- Causal ordering
- FIFO (First In First Out)
  (wrt an individual communication channel)

Total and causal ordering are independent: neither induces the other;

Causal ordering induces FIFO

Total, FIFO and Causal Ordering of Multicast Messages

Notice the consistent ordering of totally ordered messages T_1 and T_2, the FIFO-related messages F_1 and F_2 and the causally related messages C_1 and C_3 – and the otherwise arbitrary delivery ordering of messages.

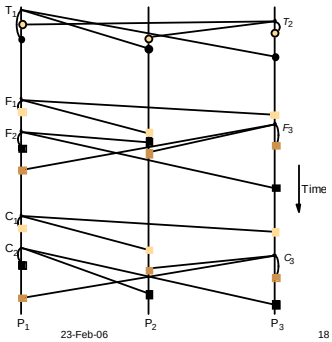


Figure 11.12

Vector Timestamps

Goal:

timestamps should reflect *causal ordering*

L(e) < L(e') => " e happened before e' "

=>

Vector clock

each process P_i maintains a vector V_i :

1. $V_i[i]$ is the number of events that have occurred at P_i
   (the current local time at P_i)
2. if $V_i[j] = k$ then P_i knows about (the first) k events that have occurred at P_j
   (the local time at P_j was k, as P_j sent the last message that P_i has received from it)

Order of Vector Timestamps

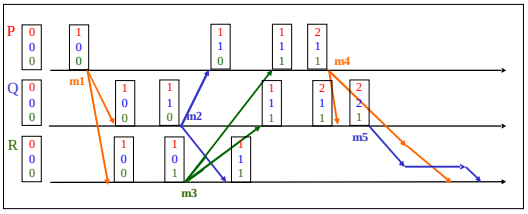
Order of timestamps

- V = V' iff V[j] = V' [j] for all j
- V ≤ V' iff V[j] ≤ V' [j] for all j
- V < V' iff V ≤ V' and V ≠ V'

Order of events *(causal order)*

- e -> e' => V(e) < V(e')
- V(e) < V(e') => e -> e'
- concurrency:
  e || e' if **not** V(e) ≤ V(e')
  and **not** V(e') ≤ V(e)

Causal Ordering of Multicasts (1)



Event: message sent

Timestamp [i,j,k] :
i messages sent from P
j messages sent form Q
k messages sent from R

R: m1 [100] m4 [211]
m2 [110] m5 [221]
m3 [101]

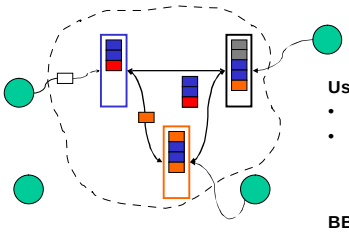
~~m3~~ [211] vs. 111

Causal Ordering of Multicasts (2)

Use of timestamps in causal multicasting

1) P_i multicast: $V_i[i] = V_i[i] + 1$
2) Message: include vt = $V_i[*]$
3) Each receiving P_j : the message **can be delivered when**
   - **vt[i] = V_j[i] + 1** *(all previous messages from P_i have arrived)*
   - for each component **k (k≠i): V_j[k] ≥ vt[k]**
     (P_j has now seen all the messages that P_i had seen when the message was sent)
4) When the message from P_i becomes deliverable at P_j the message is inserted into the delivery queue
   (notice: the delivery queue preserves causal ordering)
5) **At delivery**: $V_j[i] = V_j[i] + 1$

Causal Ordering of a Bulletin Board (1)



Assumption:
reliable, order-preserving
BB-to-BB transport

User ó BB *("local events")*

- read: bb <= BB_i (any BB)
- write: to a BB_j that contains all causal predecessors of all bb messages

BB_i => BB_j ("messages")

- BB_j must contain all nonlocal predecessors of all BB_i messages

Causal Ordering of a Bulletin Board (2)

timestamps

P_1 2 1 2 (1 2 3)

P_2 1 3 0 (1 2 3)

P_3 2 1 2 (1 2 3)

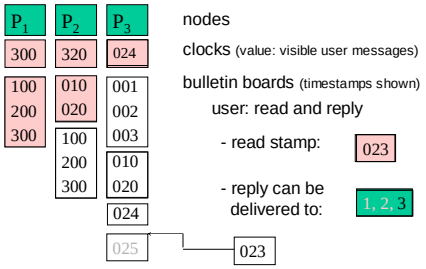
Lazy propagation of messages betw. bulletin boards
1) user => P_i
2) P_i ó P_j

vector clocks: counters

N_i messages from users to the node i

N_j messages originally received by the node j

Causal Ordering of a Bulletin Board (3)



Causal Ordering of a Bulletin Board (4)

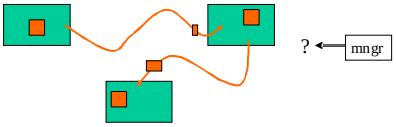
Updating of vector clocks

Process P_i

- Local vector clock $V_i[*]$
- Update due to a local event: $V_i[i] = V_i[i] + 1$

- Receiving a message with the timestamp vt [*]
  - Condition for delivery (to P_i from P_j):
    wait until for all k: k≠j: $V_i[k] \geq vt[k]$
  - Update at the delivery: $V_i[j] = vt[j]$

Global State (1)



- Needs: checkpointing, garbage collection, deadlock detection, termination, testing
- How to observe the state
  - states of processes
  - messages in transfer

A **state**: application-dependent specification

Detecting Global Properties

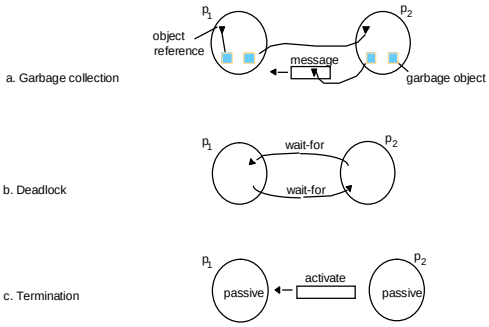


Figure 10.8

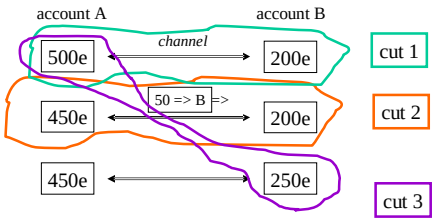
Distributed Snapshot

- Each node: history of important events
- Observer: at each node i
  - time: the local (logical) clock " T_i "
  - state S_i (history: {event, timestamp})

  => system state { S_i }
- A *cut:* the system state { S_i } "at time T"
- Requirement:
  - {Si} might have existed ó consistent with respect to some criterion
  - one possibility: consistent wrt " happened-before relation "

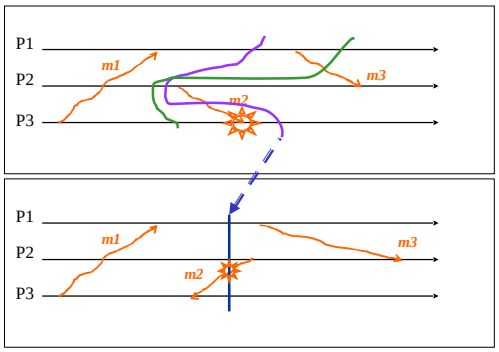
Ad-hoc State Snaphots



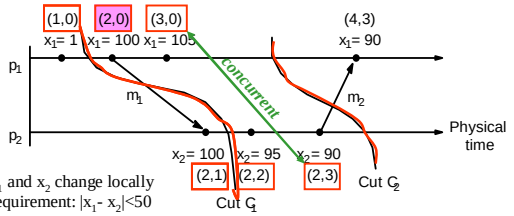
(inconsistent or) strongly consistent

state changes: money transfers A ó B
invariant: A+B = 700

Consistent and Inconsistent Cuts



Cuts and Vector Timestamps



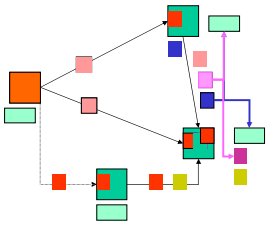
x_1 and x_2 change locally
requirement: $|x_1 - x_2| < 50$
a "large" change (">9") =>
send the new value to the other process

event: a change of the local x
=> increase the vector clock

$\{S_i\}$ system state history: all events
Cut: all events before the "cut time"

A **cut is consistent** if, for each event, it also contains all the events that "happened-before".

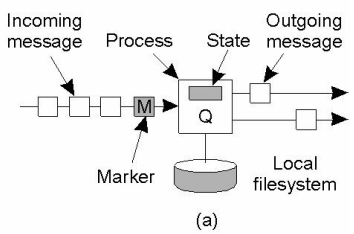
Implementation of Snapshot



Chandy, Lamport

Assumption: point-to-point, order-preserving connections

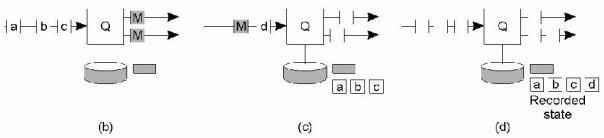
Chandy Lamport (1)



The snapshot algorithm of Chandy and Lamport

a) Organization of a process and channels for a distributed snapshot

Chandy Lamport (2)



b) Process Q receives a marker for the first time and records its local state
c) Q records all incoming messages
d) Q receives a marker for its incoming channel and finishes recording the state of this incoming channel

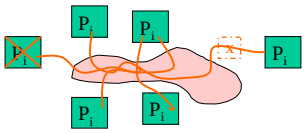
Chandy and Lamport's 'Snapshot' Algorithm

Marker receiving rule for process p_i
On p_i's receipt of a *marker* message over channel c:
if (p_i has not yet recorded its state) it
records its process state now;
records the state of c as the empty set;
turns on recording of messages arriving over other incoming channels;
else
p_i records the state of c as the set of messages it has received over c since it saved its state.
end if

Marker sending rule for process p_i
After p_i has recorded its state, for each outgoing channel c:
p_i sends one marker message over c
(before it sends any other message over c).

Figure 10.10

Coordination and Agreement

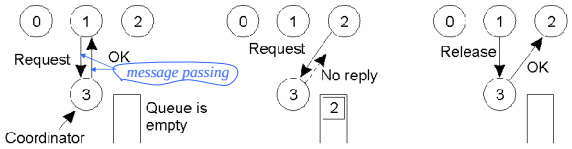


Coordination of functionality
- reservation of resources *(distributed mutual exclusion)*
- elections (coordinator, initiator)
- multicasting
- distributed transactions

Decision Making

- Centralized: one coordinator (decision maker)
  - algorithms are simple
  - no fault tolerance *(if the coordinator fails)*
- Distributed decision making
  - algorithms tend to become complex
  - may be extremely fault tolerant
  - behaviour, correctness ?
  - assumptions about failure behaviour of the platform !
- Centralized role, changing "population of the role"
  - easy: one decision maker at a time
  - challenge: management of the "role population"

Mutual Exclusion: A Centralized Algorithm (1)

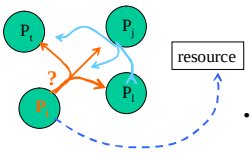


a) Process 1 asks the coordinator for permission to enter a critical region. Permission is granted
b) Process 2 then asks permission to enter the same critical region. The coordinator does not reply.
c) When process 1 exits the critical region, it tells the coordinator, which then replies to 2

Mutual Exclusion: A Centralized Algorithm (2)

- **Examples** of usage
  - a stateless server (e.g., Network File Server)
  - a separate lock server
- General **requirements** for mutual exclusion
  1. **safety**: at most one process may execute in the critical section at a time
  2. **liveness**: requests (enter, exit) eventually succeed *(no deadlock, no starvation)*
  3. **fairness** (ordering): if the request A *happens before* the request B then A is honored before B
- **Problems**: fault tolerance, performance

A Distributed Algorithm (1)



Ricart – Agrawala

- The general idea:
  - ask everybody
  - wait for permission from everybody

The problem:
- several simultaneous requests (e.g., P_i and P_j)
- all members have to agree (*everybody*: "first P_i then P_j")

Multicast Synchronization

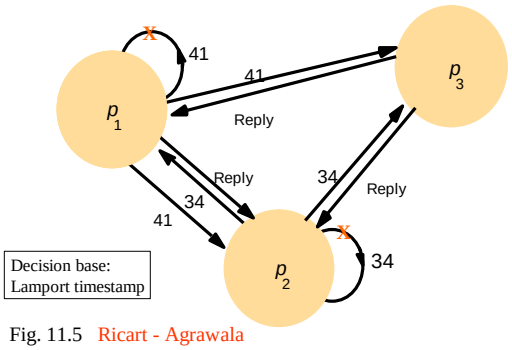


Fig. 11.5 Ricart - Agrawala

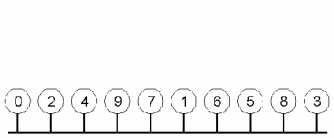
A Distributed Algorithm (2)

On initialization
  state := RELEASED;
To enter the section
  state := WANTED;
  T := request's timestamp; } request processing deferred here
  Multicast *request* to all processes;
  Wait until (number of replies received = (*N-1*));
  state := HELD;

On receipt of a request $<T_i, p_i>$ *at* p_j $(i \neq j)$
  if (*state* = HELD or (*state* = WANTED *and* $(T, p_j) < (T_i, p_i)$))
  then
    queue *request* from p_i without replying;
  else
    reply immediately to p_i;
  end if;
To exit the critical section
  state := RELEASED;
  reply to all queued requests;

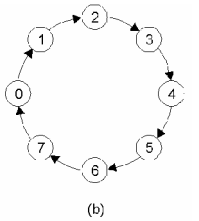
Fig. 11.4 **Ricart - Agrawala**

A Token Ring Algorithm



An unordered group of processes on a network.

(a)



(b)

A logical ring constructed in software.

Algorithm:
- token passing: straightforward
- lost token: 1) detection? 2) recovery?

Comparison

Algorithm	Messages per entry/exit	Delay before entry (in message times)	Problems
Centralized	3	2	Coordinator crash
Distributed	2 (n – 1)	2 (n – 1)	Crash of any process
Token ring	1 to ∞	0 to n – 1	Lost token, process crash

A comparison of three mutual exclusion algorithms.

Notice: the system may contain a remarkable amount of sharable resources!

Election Algorithms

- Need:
  - computation: a group of concurrent actors
  - algorithms based on the activity of a special role (coordinator, initiator)
  - election of a coordinator: initially / after some special event (e.g., the previous coordinator has disappeared)
- Premises:
  - each member of the group {Pi}
    - knows the identities of all other members
    - does not know who is up and who is down
  - all electors use the same algorithm
  - election rule: the member with the highest Pi
- Several algorithms exist

The Bully Algorithm (1)

§ P_i notices: coordinator lost
  1. Pi to {all Pj st Pj>Pi}: ELECTION!
  2. if no one responds => Pi is the coordinator
  3. some Pj responds => Pj takes over, Pi's job is done

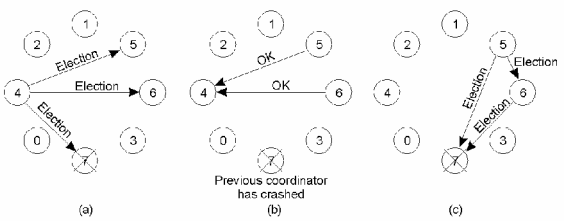
§ P_i gets an ELECTION! message:
  1. reply OK to the sender
  2. if Pi does not yet participate in an ongoing election: hold an election

§ The new coordinator P_k to everybody:
" P_k COORDINATOR"

§ P_i: ongoing election & no "P_k COORDINATOR": hold an election

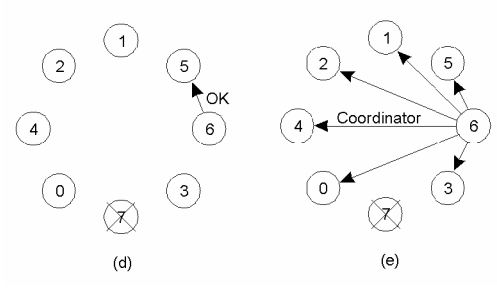
§ P_j recovers: hold an election

The Bully Algorithm (2)



The bully election algorithm
a) Process 4 holds an election
b) Process 5 and 6 respond, telling 4 to stop
c) Now 5 and 6 each hold an election

The Bully Algorithm (3)

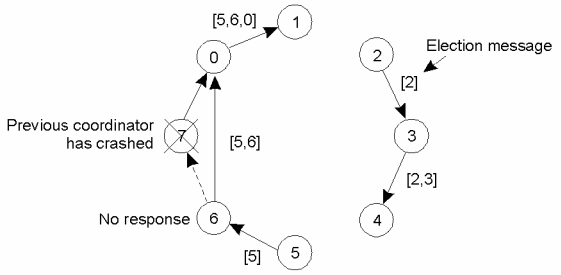


d) Process 6 tells 5 to stop
e) Process 6 wins and tells everyone

A Ring Algorithm (1)

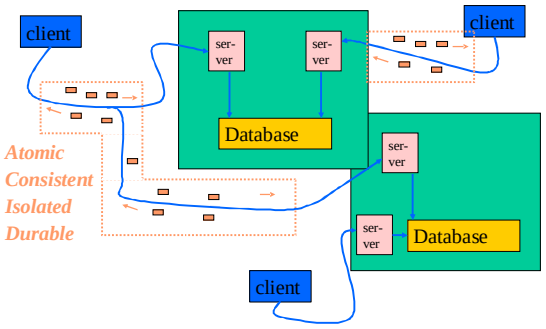
- Group {Pi} "fully connected"; election: ring
- Pi notices: coordinator lost
  - send ELECTION(Pi) to the next P
- Pj receives ELECTION(Pi)
  - send ELECTION(Pi, Pj) to successor
- . . .
- Pi receives ELECTION(..., Pi, ...)
  - active_list = {collect from the message}
  - NC = max {active_list}
  - send COORDINATOR(NC; active_list) to the next P
- …

A Ring Algorithm (2)

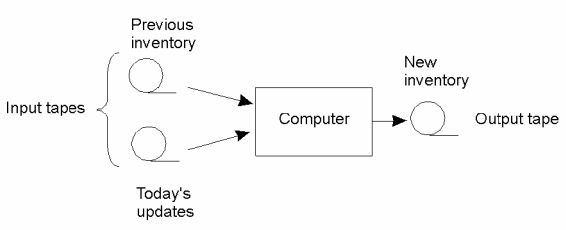


Election algorithm using a ring.

Distributed Transactions



The Transaction Model (1)



Updating a master tape is fault tolerant.

The Transaction Model (2)

Primitive	Description
BEGIN_TRANSACTION	Make the start of a transaction
END_TRANSACTION	Terminate the transaction and try to commit
ABORT_TRANSACTION	Kill the transaction and restore the old values
READ	Read data from a file, a table, or otherwise
WRITE	Write data to a file, a table, or otherwise

Examples of primitives for transactions.

The Transaction Model (3)

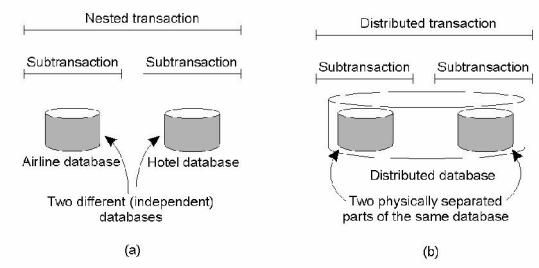
```
BEGIN_TRANSACTION
  reserve WP -> JFK;
  reserve JFK -> Nairobi;
  reserve Nairobi -> Malindi;
END_TRANSACTION
```
(a)

```
BEGIN_TRANSACTION
  reserve WP -> JFK;
  reserve JFK -> Nairobi;
  reserve Nairobi -> Malindi full =>
ABORT_TRANSACTION
```
(b)

a) Transaction to reserve three flights commits
b) Transaction aborts when third flight is unavailable

Notice:
- a transaction must have a name
- the name must be attached to each operation, which belongs to the transaction

Distributed Transactions



a) A nested transaction
b) A distributed transaction

Concurrent Transactions

- Concurrent transactions proceed in parallel
- Shared data (database)

- Concurrency-related problems (if no further transaction control):
  - lost updates
  - inconsistent retrievals
  - dirty reads
  - etc.

The lost update problem

Transaction *T* :		**Transaction *U* :**	
balance = b.getBalance();		*balance = b.getBalance();*	
*b.setBalance(balance*1.1);*		*b.setBalance(balance*1.1);*	
a.withdraw(balance/10)		*c.withdraw(balance/10)*	
balance = b.getBalance();	$200		
		balance = b.getBalance();	$200
		*b.setBalance(balance*1.1);*	$220
*b.setBalance(balance*1.1);*	$220		
a.withdraw(balance/10)	$80		
		c.withdraw(balance/10)	$280

Figure 12.5 Initial values **a**: \$100, **b**: \$200 **c**: \$300

The inconsistent retrievals problem

Transaction *V* :		**Transaction *W* :**	
a.withdraw(100)		*aBranch.branchTotal()*	
b.deposit(100)			
a.withdraw(100);	$100		
		total = a.getBalance()	$100
		total = total+b.getBalance()	$300
		total = total+c.getBalance()	
b.deposit(100)	$300	⋮	

Figure 12.6 Initial values **a**: \$200, **b**: \$200

A serially equivalent interleaving of *T* and *U*

Transaction *T* :		**Transaction *U* :**	
balance = b.getBalance()		*balance = b.getBalance()*	
*b.setBalance(balance*1.1)*		*b.setBalance(balance*1.1)*	
a.withdraw(balance/10)		*c.withdraw(balance/10)*	
balance = b.getBalance()	$200		
*b.setBalance(balance*1.1)*	$220		
		balance = b.getBalance()	$220
		*b.setBalance(balance*1.1)*	$242
a.withdraw(balance/10)	$80		
		c.withdraw(balance/10)	$278

Figure 12.7 The result corresponds the sequential execution T, U

A dirty read when transaction *T* aborts

Transaction *T*:	**Transaction *U*:**
a.getBalance()	*a.getBalance()*
a.setBalance(balance + 10)	*a.setBalance(balance + 20)*
balance = a.getBalance() **$100**	
a.setBalance(balance + 10) $110	
	balance = a.getBalance() **$110**
	a.setBalance(balance + 20) $130
	commit transaction
abort transaction	

Figure 12.11

23-Feb-06 61

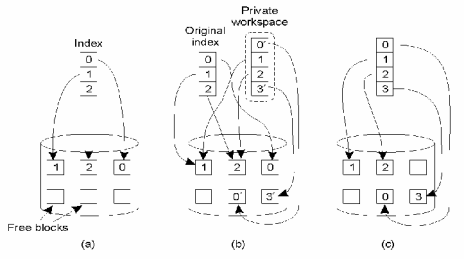
Methods for ACID

- Atomic
  - private workspace,
  - writeahead log
- Consistent

  concurrency control => serialization
  - locks
  - timestamp-based control
  - optimistic concurrency control
- Isolated (see: atomic, consistent)
- Durable (see: Fault tolerance)

23-Feb-06 62

Private Workspace



a) The file index and disk blocks for a three-block file
b) The situation after a transaction has modified block 0 and appended block 3
c) After committing

23-Feb-06 63

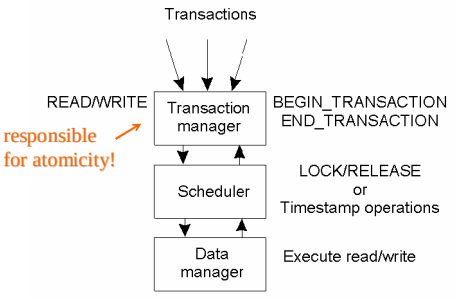
Writeahead Log

	Log	Log	Log
x = 0;			
y = 0;			
BEGIN_TRANSACTION;			
x = x + 1;	[x = 0 / 1]	[x = 0 / 1]	[x = 0 / 1]
y = y + 2		[y = 0/2]	[y = 0/2]
x = y * y;			[x = 1/4]
END_TRANSACTION;			
(a)	(b)	(c)	(d)

- a) A transaction
- b) – d) The log before each statement is executed

23-Feb-06 64

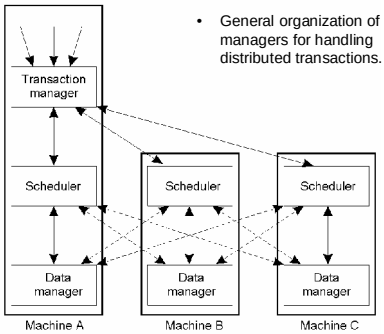
Concurrency Control (1)



General organization of managers for handling transactions.

23-Feb-06 65

Concurrency Control (2)



- General organization of managers for handling distributed transactions.

23-Feb-06 66

Serializability

```
BEGIN_TRANSACTION
 x = 0;
 x = x + 1;
END_TRANSACTION
```
(a)

```
BEGIN_TRANSACTION
 x = 0;
 x = x + 2;
END_TRANSACTION
```
(b)

```
BEGIN_TRANSACTION
 x = 0;
 x = x + 3;
END_TRANSACTION
```
(c)

Schedule 1	x = 0; x = x + 1; x = 0; x = x + 2; x = 0; x = x + 3	Legal
Schedule 2	x = 0; x = 0; x = x + 1; x = x + 2; x = 0; x = x + 3;	Legal
Schedule 3	x = 0; x = 0; x = x + 1; x = 0; x = x + 2; x = x + 3;	Illegal

(d)

a) – c) Three transactions T_1, T_2, and T_3; d) Possible schedules
Legal: there exists a serial execution leading to the same result.

Implementation of Serializability

Decision making: the transaction scheduler

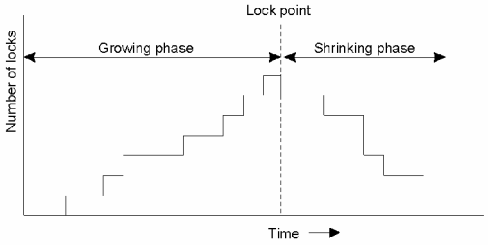
- Locks
  - data item ~ lock
  - request for operation
    - a corresponding lock (read/write) is granted OR
    - the operation is delayed until the lock is released
- Pessimistic timestamp ordering
  - transaction <= timestamp; data item <= R-, W-stamps
  - each request for operation:
    - check serializability
    - continue, wait, abort
- Optimistic timestamp ordering
  - serializability check: at END_OF_TRANSACTION, only

Transactions *T* and *U* with Exclusive Locks

Transaction *T*: *balance = b.getBalance()* *b.setBalance(bal*1.1)* *a.withdraw(bal/10)*		**Transaction *U*:** *balance = b.getBalance()* *b.setBalance(bal*1.1)* *c.withdraw(bal/10)*	
Operations	Locks	Operations	Locks
openTransaction			
bal = b.getBalance()	lock *B*		
*b.setBalance(bal*1.1)*		*openTransaction*	
a.withdraw(bal/10)	lock *A*	*bal = b.getBalance()*	waits for *T*'s lock on *B*
closeTransaction	unlock *A*, *B*	•••	
			lock *B*
		*b.setBalance(bal*1.1)*	
		c.withdraw(bal/10)	lock *C*
		closeTransaction	unlock *B*, *C*

Figure 12.14

Two-Phase Locking (1)

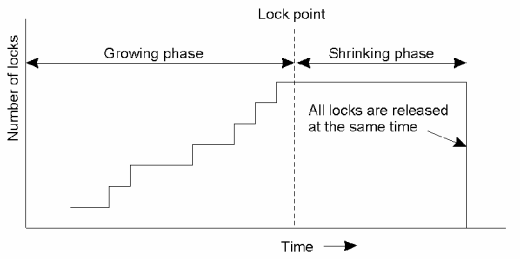


Two-phase locking (2PL).

Releases: application controlled

Problem: dirty reads?

Two-Phase Locking (2)



Strict two-phase locking.

Centralized or distributed.

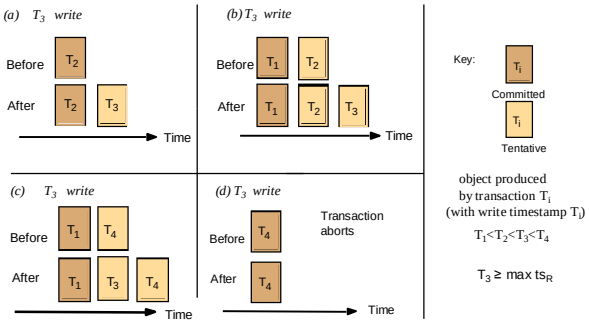
Pessimistic Timestamp Ordering

- Transaction timestamp ts(T)
  - given at BEGIN_TRANSACTION (must be unique!)
  - attached to each operation
- Data object timestamps $ts_{RD}(x)$, $ts_{WR}(x)$
  - $ts_{RD}(x)$ = ts(T) of the last T which read x
  - $ts_{wr}(x)$ = ts(T) of the last T which changed x
- Required serial equivalence: ts(T) order of T's

Pessimistic Timestamp Ordering

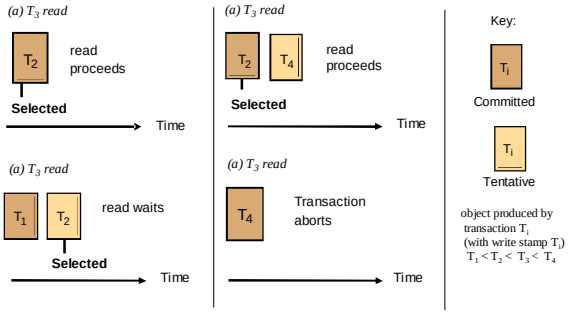
- The rules:
  - you are not allowed to change what later transactions already have seen (or changed!)
  - you are not allowed to read what later transactions already have changed
- Conflicting operations
  - process the older transaction first
  - violation of rules: the transaction is aborted (i.e., the older one: it is too late!)
  - if tentative versions are used, the final decision is made at END_TRANSACTION

Write Operations and Timestamps



CoDoKi: Figure 12.30

Read Operations and Timestamps

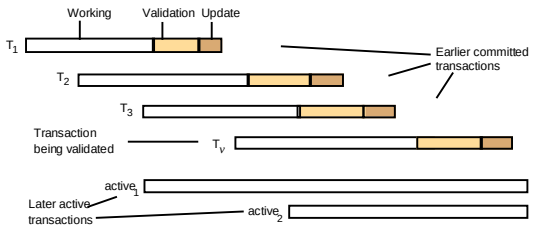


CoDoKi: Figure 12.31

Optimistic Timestamp Ordering

- Problems with locks
  - general overhead (must be done whether needed or not)
  - possibility of deadlock
  - duration of locking (=> end of the transaction)
- Problems with pessimistic timestamps
  - overhead
- Alternative
  - proceed to the end of the transaction
  - validate
  - applicable if the probability of conflicts is low

Validation of Transactions



CoDoKi: Figure 12.28

Validation of Transactions

Backward validation of transaction T_v

```
boolean valid = true;
for (int Ti = startTn+1; Ti <= finishTn; Ti++){
        if (read set of Tv intersects write set of Ti) valid = false;
}
```

Forward validation of transaction T_v

```
boolean valid = true;
for (int Tid = active1; Tid <= activeN; Tid++){
        if (write set of Tv intersects read set of Tid) valid = false;
}
```

CoDoKi: Page 499-500
