3. Approximate String Matching

Often in applications we want to search a text for something that is similar to the pattern but not necessarily exactly the same.

To formalize this problem, we have to specify what does “similar” mean. This can be done by defining a similarity or a distance measure.

A natural and popular distance measure for strings is the edit distance, also known as the Levenshtein distance.
Edit distance

The edit distance $ed(A, B)$ of two strings $A$ and $B$ is the minimum number of edit operations needed to change $A$ into $B$. The allowed edit operations are:

S  Substitution of a single character with another character.

I  Insertion of a single character.

D  Deletion of a single character.

Example 3.1: Let $A = \text{Lewensteinn}$ and $B = \text{Levenshtein}$. Then $ed(A, B) = 3$.

The set of edit operations can be described

with an edit sequence:  NNSNNNINNNND
or with an alignment:  Lewens-teinn
Levenshtein-

In the edit sequence, N means No edit.
There are many variations and extension of the edit distance, for example:

- **Hamming distance** allows only the substitution operation.
- **Damerau–Levenshtein distance** adds an edit operation:
  - **Transposition** swaps two adjacent characters.
- With **weighted edit distance**, each operation has a cost or weight, which can be other than one.
- Allow insertions and deletions (indels) of **factors** at a cost that is lower than the sum of character indels.

We will focus on the basic Levenshtein distance.

Levenshtein distance has the following two useful properties, which are not shared by all variations (exercise):

- Levenshtein distance is a **metric**.
- If \( ed(A, B) = k \), there exists an edit sequence and an alignment with \( k \) edit operations, but no edit sequence or alignment with less than \( k \) edit operations. An edit sequence and an alignment with \( ed(A, B) \) edit operations is called **optimal**.
Computing Edit Distance

Given two strings $A[1..m]$ and $B[1..n]$, define the values $d_{ij}$ with the recurrence:

$$
\begin{align*}
  d_{00} &= 0, \\
  d_{i0} &= i, \quad 1 \leq i \leq m, \\
  d_{0j} &= j, \quad 1 \leq j \leq n, \quad \text{and} \\
  d_{ij} &= \min \left\{ \begin{array}{ll}
    d_{i-1,j-1} + \delta(A[i], B[j]) \\
    d_{i-1,j} + 1 & 1 \leq i \leq m, 1 \leq j \leq n, \\
    d_{i,j-1} + 1 \\
  \end{array} \right. \\
\end{align*}
$$

where

$$
\delta(A[i], B[j]) = \begin{cases} 
  1 & \text{if } A[i] \neq B[j] \\
  0 & \text{if } A[i] = B[j] 
\end{cases}
$$

**Theorem 3.2:** $d_{ij} = ed(A[1..i], B[1..j])$ for all $0 \leq i \leq m, 0 \leq j \leq n$. In particular, $d_{mn} = ed(A, B)$. 

113
**Example 3.3:** $A =$ ballad, $B =$ handball

<table>
<thead>
<tr>
<th>$d$</th>
<th>handball</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1 2 3 4 5 6 7 8</td>
</tr>
<tr>
<td>b</td>
<td>1 1 2 3 4 4 5 6 7</td>
</tr>
<tr>
<td>a</td>
<td>2 2 1 2 3 4 5 6</td>
</tr>
<tr>
<td>l</td>
<td>3 3 2 2 3 4 5 4 5</td>
</tr>
<tr>
<td>l</td>
<td>4 4 3 3 3 4 5 5 4</td>
</tr>
<tr>
<td>a</td>
<td>5 5 4 4 4 4 5 5 4</td>
</tr>
<tr>
<td>d</td>
<td>6 6 5 5 4 5 5 5 6</td>
</tr>
</tbody>
</table>

$ed(A, B) = d_{mn} = d_{6,8} = 6.$
Proof of Theorem 3.2. We use induction with respect to $i + j$. For brevity, write $A_i = A[1..i]$ and $B_j = B[1..j]$.

**Basis:**
\[
\begin{align*}
d_{00} &= 0 = ed(\epsilon, \epsilon) \\
d_{i0} &= i = ed(A_i, \epsilon) \quad (i \text{ deletions}) \\
d_{0j} &= j = ed(\epsilon, B_j) \quad (j \text{ insertions})
\end{align*}
\]

**Induction step:** We show that the claim holds for $d_{ij}$, $1 \leq i \leq m$, $1 \leq j \leq n$.

By induction assumption, $d_{pq} = ed(A_p, B_q)$ when $p + q < i + j$.

Let $E_{ij}$ be an optimal edit sequence with the cost $ed(A_i, B_j)$. We have three cases depending on what the last operation symbol in $E_{ij}$ is:

**N or S:** $E_{ij} = E_{i-1,j-1}N$ or $E_{ij} = E_{i-1,j-1}S$ and
\[
ed(A_i, B_j) = ed(A_{i-1}, B_{j-1}) + \delta(A[i], B[j]) = d_{i-1,j-1} + \delta(A[i], B[j]).
\]

**I:** $E_{ij} = E_{i,j-1}I$ and $ed(A_i, B_j) = ed(A_i, B_{j-1}) + 1 = d_{i,j-1} + 1$.

**D:** $E_{ij} = E_{i-1,j}D$ and $ed(A_i, B_j) = ed(A_{i-1}, B_j) + 1 = d_{i-1,j} + 1$.

One of the cases above is always true, and since the edit sequence is optimal, it must be one with the minimum cost, which agrees with the definition of $d_{ij}$. □
The recurrence gives directly a dynamic programming algorithm for computing the edit distance.

**Algorithm 3.4:** Edit distance

**Input:** strings $A[1..m]$ and $B[1..n]$

**Output:** $ed(A,B)$

1. for $i \leftarrow 0$ to $m$ do $d_{i0} \leftarrow i$
2. for $j \leftarrow 1$ to $n$ do $d_{0j} \leftarrow j$
3. for $j \leftarrow 1$ to $n$ do
4. for $i \leftarrow 1$ to $m$ do
5. $d_{ij} \leftarrow \min\{d_{i-1,j-1} + \delta(A[i], B[j]), d_{i-1,j} + 1, d_{i,j-1} + 1\}$
6. return $d_{mn}$

The time and space complexity is $O(mn)$. 
The space complexity can be reduced by noticing that each column of the
matrix \((d_{ij})\) depends only on the previous column. We do not need to store
older columns.

A more careful look reveals that, when computing \(d_{ij}\), we only need to store
the bottom part of column \(j - 1\) and the already computed top part of
column \(j\). We store these in an array \(C[0..m]\) and variables \(c\) and \(d\) as shown
below:
Algorithm 3.5: Edit distance in $O(m)$ space

Input: strings $A[1..m]$ and $B[1..n]$

Output: $ed(A,B)$

(1) for $i \leftarrow 0$ to $m$ do $C[i] \leftarrow i$

(2) for $j \leftarrow 1$ to $n$ do

(3) $c \leftarrow C[0]; C[0] \leftarrow j$

(4) for $i \leftarrow 1$ to $m$ do

(5) $d \leftarrow \min\{c + \delta(A[i], B[j]), C[i - 1] + 1, C[i] + 1\}$

(6) $c \leftarrow C[i]$

(7) $C[i] \leftarrow d$

(8) return $C[m]$

Note that because $ed(A,B) = ed(B,A)$ (exercise), we can always choose $A$ to be the shorter string so that $m \leq n$. 

118
It is also possible to find optimal edit sequences and alignments from the matrix $d_{ij}$.

An edit graph is a directed graph, where the nodes are the cells of the edit distance matrix, and the edges are as follows:

- If $A[i] = B[j]$ and $d_{ij} = d_{i-1,j-1}$, there is an edge $(i-1,j-1) \rightarrow (i,j)$ labelled with N.
- If $A[i] \neq B[j]$ and $d_{ij} = d_{i-1,j-1} + 1$, there is an edge $(i-1,j-1) \rightarrow (i,j)$ labelled with S.
- If $d_{ij} = d_{i,j-1} + 1$, there is an edge $(i,j-1) \rightarrow (i,j)$ labelled with I.
- If $d_{ij} = d_{i-1,j} + 1$, there is an edge $(i-1,j) \rightarrow (i,j)$ labelled with D.

Any path from $(0,0)$ to $(m,n)$ is labelled with an optimal edit sequence.
Example 3.6: \( A = \text{ballad}, B = \text{handball} \)

There are 7 paths from \((0, 0)\) to \((6, 8)\) corresponding to 7 different optimal edit sequences and alignments, including the following three:

- IIIINNNNDD  SNISSNIS  SNSSINSI
  - ballad  ballad
- I-I-I  ball-ad  ball-ad
- handball--  handball  handball

<table>
<thead>
<tr>
<th></th>
<th>h a n d b b a l l</th>

</table>
Approximate String Matching

Now we are ready to tackle the main problem of this part: approximate string matching.

**Problem 3.7:** Given a text $T[1..n]$, a pattern $P[1..m]$ and an integer $k \geq 0$, report all positions $j \in [1..m]$ such that $ed(P, T(j - \ell...j)) \leq k$ for some $\ell \geq 0$.

The factor $T(j - \ell...j]$ is called an approximate occurrence of $P$.

There can be multiple occurrences of different lengths ending at the same position $j$, but usually it is enough to report just the end positions. We ask for the end position rather than the start position because that is more natural for the algorithms.
Define the values $g_{ij}$ with the recurrence:

$$g_{0j} = 0, \quad 0 \leq j \leq n,$$
$$g_{i0} = i, \quad 1 \leq i \leq m,$$
and

$$g_{ij} = \min \left\{ \begin{array}{ll}
g_{i-1,j-1} + \delta(P[i], T[j]) \\
g_{i-1,j} + 1 \\
g_{i,j-1} + 1 \\
\end{array} \right\} \quad 1 \leq i \leq m, 1 \leq j \leq n.$$ 

**Theorem 3.8:** For all $0 \leq i \leq m, 0 \leq j \leq n$:

$$g_{ij} = \min \{ ed(P[1..i], T(j-\ell...j)) \mid 0 \leq \ell \leq j \} .$$

In particular, $j$ is an ending position of an approximate occurrence if and only if $g_{mj} \leq k$. 

122
Proof. We use induction with respect to $i + j$.

Basis:

\[
\begin{align*}
g_{00} &= 0 = ed(\epsilon, \epsilon) \\
g_{0j} &= 0 = ed(\epsilon, \epsilon) = ed(\epsilon, T(j - 0..j]) \quad \text{(min at } \ell = 0) \\
g_{i0} &= i = ed(P[1..i], \epsilon) = ed(P[1..i], T(0 - 0..0]) \quad (0 \leq \ell \leq j = 0)
\end{align*}
\]

Induction step: Essentially the same as in the proof of Theorem 3.2.
Example 3.9: $P = \text{match}$, $T = \text{remachine}$, $k = 1$

<table>
<thead>
<tr>
<th></th>
<th>r</th>
<th>e</th>
<th>m</th>
<th>a</th>
<th>c</th>
<th>h</th>
<th>i</th>
<th>n</th>
<th>e</th>
</tr>
</thead>
<tbody>

<td>4</td>
<td>4</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
<tr>
<td></td>
<td>5</td>
<td>5</td>
<td>5</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
</tbody>
</table>

One occurrence ending at position 6.
Algorithm 3.10: Approximate string matching
Input: text $T[1..n]$, pattern $P[1..m]$, and integer $k$
Output: end positions of all approximate occurrences of $P$

(1) for $i \leftarrow 0$ to $m$ do $g_{i0} \leftarrow i$
(2) for $j \leftarrow 1$ to $n$ do $g_{0j} \leftarrow 0$
(3) for $j \leftarrow 1$ to $n$ do
(4) for $i \leftarrow 1$ to $m$ do
(5) $g_{ij} \leftarrow \min\{g_{i-1,j-1} + \delta(A[i],B[j]), g_{i-1,j} + 1, g_{i,j-1} + 1\}$
(6) if $q_{mj} \leq k$ then output $j$

- Time and space complexity is $O(mn)$ on ordered alphabet.
- The space complexity can be reduced to $O(m)$ by storing only one column as in Algorithm 3.5.
Ukkonen's Cut-off Heuristic

We can speed up the algorithm using the diagonal monotonicity of the matrix \((g_{ij})\):

A diagonal \(d, -m \leq d \leq n\), consists of the cells \(g_{ij}\) with \(j - i = d\).

Every diagonal in \((g_{ij})\) is monotonically non-decreasing.

Example 3.11: Diagonals -3 and 2.

<table>
<thead>
<tr>
<th></th>
<th>r</th>
<th>e</th>
<th>m</th>
<th>a</th>
<th>c</th>
<th>h</th>
<th>i</th>

<tr>
<td>m</td>
<td></td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>a</td>
<td></td>
<td></td>
<td>2</td>
<td>2</td>
<td>2</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>t</td>
<td></td>
<td></td>
<td></td>
<td>3</td>
<td>3</td>
<td>3</td>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>c</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>4</td>
<td>4</td>
<td>3</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>h</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td>5</td>
<td>5</td>
<td>4</td>
<td>3</td>
</tr>
</tbody>
</table>
Lemma 3.12: For every \( i \in [1..m] \) and every \( j \in [1..n] \),
\[ g_{ij} = g_{i-1,j-1} \text{ or } g_{ij} = g_{i-1,j-1} + 1. \]

Proof. By definition, \( g_{ij} \leq g_{i-1,j-1} + \delta(P[i], T[j]) \leq g_{i-1,j-1} + 1 \). We show that \( g_{ij} \geq g_{i-1,j-1} \) by induction on \( i + j \).

The induction assumption is that \( g_{pq} \geq g_{p-1,q-1} \) when \( p \in [1..m], q \in [1..n] \) and \( p + q < i + j \). At least one of the following holds:

1. \( g_{ij} = g_{i-1,j-1} + \delta(P[i], T[j]) \). Then \( g_{ij} \geq g_{i-1,j-1} \).
2. \( g_{ij} = g_{i-1,j} + 1 \) and \( i > 1 \). Then
   \[
   g_{ij} = g_{i-1,j} + 1 \quad \text{ind. assump.} \quad \geq g_{i-2,j-1} + 1 \quad \text{definition} \quad \geq g_{i-1,j-1}
   \]
3. \( g_{ij} = g_{i,j-1} + 1 \) and \( j > 1 \). Then
   \[
   g_{ij} = g_{i,j-1} + 1 \quad \text{ind. assump.} \quad \geq g_{i-1,j-2} + 1 \quad \text{definition} \quad \geq g_{i-1,j-1}
   \]
4. \( g_{ij} = g_{i-1,j} + 1 \) and \( i = 1 \). Then \( g_{ij} = 0 + 1 > 0 = g_{i-1,j-1} \).
5. \( g_{ij} = g_{i,j-1} + 1 \) and \( j = 1 \). Then \( g_{ij} = i + 1 = (i - 1) + 2 = g_{i-1,j-1} + 2 \),
which cannot be true. Thus this case can never happen. \( \square \)
We can reduce computation using diagonal monotonicity:

- Whenever the value on a diagonal $d$ grows larger than $k$, we can discard $d$ from consideration, because we are only interested in values at most $k$ on the row $m$.
- We keep track of the smallest undiscarded diagonal $d$. Each column is computed only up to diagonal $d + 1$.

**Example 3.13:** $P = \text{strict}$, $T = \text{datastructure}$, $k = 1$

<table>
<thead>
<tr>
<th>g</th>
<th>datastructure</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 0 0 0 0 0 0 0 0 0 0 0 0 0</td>
</tr>
<tr>
<td>s</td>
<td>1 1 1 1 1 1 1 1 1 1 1 1 1 1</td>
</tr>
<tr>
<td>t</td>
<td>2 2 2 1 2 1 0 1 2 2 1 2 2 2</td>
</tr>
<tr>
<td>r</td>
<td>2 2 2 1 0 1 2 2 2</td>
</tr>
<tr>
<td>i</td>
<td>2 1 1 2 3 3</td>
</tr>
<tr>
<td>c</td>
<td>2 2 1 2 3</td>
</tr>
<tr>
<td>t</td>
<td>2 1 2</td>
</tr>
</tbody>
</table>
The position of the smallest undiscarded diagonal on the current column is kept in a variable \( \text{top} \).

**Algorithm 3.14:** Ukkonen’s cut-off algorithm  

**Input:** text \( T[1..n] \), pattern \( P[1..m] \), and integer \( k \)  

**Output:** end positions of all approximate occurrences of \( P \)  

1. \( \text{top} \leftarrow \min(k + 1, m) \)  
2. for \( i \leftarrow 0 \) to \( \text{top} \) do \( g_{i0} \leftarrow i \)  
3. for \( j \leftarrow 1 \) to \( n \) do \( g_{0j} \leftarrow 0 \)  
4. for \( j \leftarrow 1 \) to \( n \) do  
5. for \( i \leftarrow 1 \) to \( \text{top} \) do  
6. \( g_{ij} \leftarrow \min\{g_{i-1,j-1} + \delta(A[i], B[j]), g_{i-1,j} + 1, g_{i,j-1} + 1\} \)  
7. while \( g_{\text{top},j} > k \) do \( \text{top} \leftarrow \text{top} - 1 \)  
8. if \( \text{top} = m \) then output \( j \)  
9. else \( \text{top} \leftarrow \text{top} + 1; \ g_{\text{top},j} \leftarrow k + 1 \)
The time complexity is proportional to the computed area in the matrix \((g_{ij})\).

- The worst case time complexity is still \(O(mn)\) on ordered alphabet.
- The average case time complexity is \(O(kn)\). The proof is not trivial.

There are many other algorithms based on diagonal monotonicity. Some of them achieve \(O(kn)\) worst case time complexity.
